

DONALDSON-THOMAS INVARIANTS OF LOCAL ELLIPTIC SURFACES VIA THE TOPOLOGICAL VERTEX

JIM BRYAN AND MARTIJN KOOL

ABSTRACT. We compute the Donaldson-Thomas invariants of a local elliptic surface with section. We introduce a new computational technique which is a mixture of motivic and toric methods. This allows us to write the partition function for the invariants in terms of the topological vertex. Utilizing identities for the topological vertex proved in [6], we derive product formulas for the partition functions. The connected version of the partition function is written in terms of Jacobi forms. In the special case where the elliptic surface is a K3 surface, we get a derivation of the Katz-Klemm-Vafa formula for primitive curve classes which is independent of the computation of Kawai-Yoshioka.

1. INTRODUCTION

Let $p : S \rightarrow B$ be a non-trivial elliptic surface over a complex smooth projective curve B . We assume p has a section and all singular fibers are irreducible rational nodal curves.

In this paper, we study the Donaldson-Thomas (DT) invariants of $X = \text{Tot}(K_S)$, i.e. the total space of the canonical bundle K_S . This is a non-compact Calabi-Yau threefold. Let β be an effective curve class on S . Consider the Hilbert scheme

$$\text{Hilb}^{\beta,n}(X) = \{Z \subset X : [Z] = \beta, \chi(\mathcal{O}_Z) = n\}$$

of proper subschemes $Z \subset X$ with homology class β and holomorphic Euler characteristics n . The DT invariants of X can be defined as

$$\text{DT}_{\beta,n}(X) := e(\text{Hilb}^{\beta,n}(X), \nu) := \sum_{k \in \mathbb{Z}} k e(\nu^{-1}(k)),$$

where $e(\cdot)$ denotes topological Euler characteristic and $\nu : \text{Hilb}^{\beta,n}(X) \rightarrow \mathbb{Z}$ is Behrend's constructible function [2]. We also consider an unweighted Euler characteristic version of these invariants

$$\widehat{\text{DT}}_{\beta,n}(X) := e(\text{Hilb}^{\beta,n}(X)).$$

Date: July 13, 2018.

We choose a section $B \subset S$ and focus on the primitive classes $\beta = B + dF$, where B is the class of the chosen section and F the class of the fiber. We define the partition functions by

$$\begin{aligned}\widehat{\text{DT}}(X) &= \sum_{d=0}^{\infty} \sum_{n \in \mathbb{Z}} \widehat{\text{DT}}_{B+dF,n}(X) p^n q^d, \\ \text{DT}(X) &= \sum_{d=0}^{\infty} \sum_{n \in \mathbb{Z}} \text{DT}_{B+dF,n}(X) y^n q^d.\end{aligned}$$

We also consider the partition functions for the invariants for multiples of the fiber class

$$\begin{aligned}\widehat{\text{DT}}_{\text{fib}}(X) &= \sum_{d \geq 0} \sum_{n \in \mathbb{Z}} \widehat{\text{DT}}_{dF,n}(X) p^n q^d, \\ \text{DT}_{\text{fib}}(X) &= \sum_{d \geq 0} \sum_{n \in \mathbb{Z}} \text{DT}_{dF,n}(X) y^n q^d.\end{aligned}$$

The main result of this paper are closed product formulas for the partition functions $\widehat{\text{DT}}(X)$ and $\widehat{\text{DT}}_{\text{fib}}(X)$. Assuming a general conjecture about the Behrend function, we also determine $\text{DT}(X)$ and $\text{DT}_{\text{fib}}(X)$.

We use the notation

$$M(p, q) = \prod_{m=1}^{\infty} (1 - p^m q)^{-m}$$

and the shorthand $M(p) = M(p, 1)$.

Theorem 1. *Let $e(S)$ and $e(B)$ denote the topological Euler characteristic of the elliptic surface and the base. Then*

$$\begin{aligned}\widehat{\text{DT}}(X) &= \left\{ M(p) \prod_{d=1}^{\infty} \frac{M(p, q^d)}{(1 - q^d)} \right\}^{e(S)} \left\{ \frac{1}{(p^{\frac{1}{2}} - p^{-\frac{1}{2}})} \prod_{d=1}^{\infty} \frac{(1 - q^d)}{(1 - pq^d)(1 - p^{-1}q^d)} \right\}^{e(B)} \\ \widehat{\text{DT}}_{\text{fib}}(X) &= \left\{ M(p) \prod_{d=1}^{\infty} M(p, q^d) \right\}^{e(S)} \left\{ \prod_{d=1}^{\infty} \frac{1}{(1 - q^d)} \right\}^{e(B)}.\end{aligned}$$

The formula for $\widehat{\text{DT}}_{\text{fib}}(X)$ was previously proved using wall-crossing methods by Toda¹.

The ratio $\widehat{\text{DT}}(X)/\widehat{\text{DT}}_{\text{fib}}(X)$ can be considered as the generating function for the connected invariants in the classes $B + dF$. This series has a particularly nice form and can be written in terms of classical Jacobi forms.

¹After applying the PT/DT correspondence [4], this is essentially [19, Thm 6.9].

Consider the Dedekind eta function and the Jacobi theta function

$$\eta = q^{\frac{1}{24}} \prod_{k=1}^{\infty} (1 - q^k),$$

$$\Theta = (p^{\frac{1}{2}} - p^{-\frac{1}{2}}) \prod_{k=1}^{\infty} \frac{(1 - pq^k)(1 - p^{-1}q^k)}{(1 - q^k)^2}.$$

Corollary 2. *The partition function of the connected invariants is given as follows*

$$\frac{\widehat{\text{DT}}(X)}{\widehat{\text{DT}}_{\text{fib}}(X)} = \left(q^{-\frac{1}{24}} \eta \right)^{-e(S)} \Theta^{-e(B)}.$$

In the case where $S \rightarrow \mathbb{P}^1$ is an elliptically fibered K3 surface, the above series specializes (up to a factor of q) to the reciprocal of $\eta^{24}\Theta^2$, the unique Jacobi cusp form of weight 10 and index 1. This is the Jacobi form appearing in the well-known Katz-Klemm-Vafa formula. In order to obtain the KKV formula, we require the connected series, because X is non-compact.

Our result provides a new derivation of the KKV formula for primitive classes². The KKV formula was proved in all curve classes in [17]. The appearance of the Jacobi form $\eta^{24}\Theta^2$ in previous proofs of the KKV formula [14, 17] ultimately comes from the calculation of Euler characteristics of relative Hilbert schemes of points on curves on K3 by Kawai-Yoshioka [10]. Our derivation of the KKV formula is the first that does not depend on the Kawai-Yoshioka formula.

Our results can be extended to apply to the usual (Behrend function weighted) Donaldson-Thomas invariants if we assume a general conjecture that we formulate in Section 8. Our conjecture relates the Behrend function at subschemes with embedded points to the value of the Behrend function at the underlying Cohen-Macaulay subscheme and may be of independent interest.

Theorem 3. *Assume that Conjecture 18 holds, then*

$$\text{DT}(X) = (-1)^{\chi(\mathcal{O}_S)} \widehat{\text{DT}}(X)$$

and

$$\text{DT}_{\text{fib}}(X) = \widehat{\text{DT}}_{\text{fib}}(X)$$

under the change of variables

$$y = -p.$$

²At least for the Euler characteristic version of the Donaldson-Thomas invariants. For the Behrend function weighted Donaldson-Thomas invariants, we require Conjecture 18, see Theorem 3 below.

A similar phenomenon to the above is known to hold when X is a toric Calabi-Yau threefold.

The method of computation that we have introduced in this paper has been applied to other elliptically fibered geometries. Indeed, it has found applications to the calculation of DT generating functions on $K3 \times E$, where E is an elliptic curve [5] and abelian threefolds [7], and is expected to apply to $(K3 \times E)/G$ where G is a finite group acting symplectically on each factor. Even though the geometry under consideration is not toric, we combine \mathbb{C}^* -localization, motivic methods, formal methods, and $(\mathbb{C}^*)^3$ -localization to end up with expressions that only depend on the topological vertex $V_{\lambda\mu\nu}$, and the topological Euler characteristics $e(B)$ and $e(S)$. The outline of our method is as follows:

- The \mathbb{C}^* -action on X induces an action on $\text{Hilb}(X)$ whose Euler characteristic localizes to the \mathbb{C}^* -fixed locus. In Section 3 we show that any \mathbb{C}^* -invariant subscheme has a maximal Cohen-Macaulay subscheme which is a curve of a special form which we call a partition thickened comb curve (Definition 6). This curve is determined by data consisting of points $x_i \in B$ labelled by integer partitions $\lambda^{(i)}$. This gives rise to a constructible morphism ρ to $\text{Sym } B$ taking the value $\sum_i |\lambda^{(i)}| x_i$ on such a curve (see Theorem 7).
- In Section 4, we push forward the Euler characteristic measure to $\text{Sym } B$ via the map ρ . We show that $\rho_*(1)$, the push-forward measure, has nice multiplicative properties that allow us to compute the weighted Euler characteristic over $\text{Sym } B$ using a general result about symmetric products (Lemma 29).
- To compute the push-forward measure $\rho_*(1)$ explicitly, we must compute the Euler characteristics of the fibers of ρ . These fibers are strata in the Hilbert scheme parameterizing subschemes whose maximal Cohen-Macaulay subscheme is a fixed partition thickened comb curve C . The moduli of this stratum come solely from the ways in which embedded points and zero dimensional components can be added to C . We write this stratum as a product of “local” Hilbert schemes using an fpqc cover of X which includes the formal neighborhoods of the nodal points of C_{red} , the formal neighborhoods of the components of C_{red} (minus the nodes), and the complement of C . This is done in Section 5.
- After further push-forwards to further symmetric products, we reduce our expression for $\rho_*(1)$ (and hence our expression for $\widehat{\text{DT}}(X)$) to an expression only involving the Euler characteristics of the local Hilbert schemes of formal neighborhoods of points. Since these formal neighborhoods are isomorphic to $\widehat{\mathbb{C}}_0^3 = \text{Spec } \mathbb{C}[[r, s, t]]$, they

admit a $T = (\mathbb{C}^*)^3$ -action. T -localization then allows us to write these Euler characteristics in terms of the topological vertex (see Section 6).

- Finally, using the trace formulas for the topological vertex proved in [6], we write our expression for $\widehat{\text{DT}}(X)$ as the closed product formula given in Theorem 1.

Our proof of Theorem 3 requires Theorem 21, an involved computation of $\text{Ext}_0^1(I_C, I_C)$ for partition thickened comb curves C . The proof of Theorem 21 occupies most of Section 9 and while technical in nature, the method we introduce (again a mixture of formally local toric methods and global geometry) may be of independent interest to the experts.

1.1. Acknowledgments.

The authors would like to thank Tom Graber, Paul Johnson, Manfred Lehn, Oliver Leigh, Daves Maulik, Georg Oberdieck, Rahul Pandharipande, Jørgen Rennemo, Balázs Szendrői, Richard Thomas, Qizheng Yin, and Benjamin Young for helpful conversations.

Part of this work was done during the semester *Enumerative geometry of moduli spaces of sheaves in low dimension* at CIB/EPFL, who provided support and excellent working conditions.

2. DEFINITIONS, NOTATION, AND CONVENTIONS

Let $p : S \rightarrow B$ be an elliptic surface over a smooth projective curve B . We assume:

- (1) S is a non-trivial fibration,
- (2) p has a section $B \subset S$,
- (3) all singular fibers of p are irreducible rational nodal curves.

We note that the number of singular fibers is equal to $e(S)$.

We write F_x for the fiber $p^{-1}(x)$ over a point $x \in B$. We choose a section $B \subset S$ and denote its class in $H_2(S)$ by B as well. We denote the class of the fiber by $F \in H_2(S)$.

For brevity, we define

$$\begin{aligned} \text{Hilb}^{d,n}(X) &:= \text{Hilb}^{B+dF,n}(X), \\ \widehat{\text{DT}}_{d,n}(X) &:= \widehat{\text{DT}}_{B+dF,n}(X). \end{aligned}$$

Since we are dealing with generating functions and our calculations involve motivic methods on the Hilbert schemes, it is useful to introduce the

following notation. We define

$$\mathrm{Hilb}^{d,\bullet}(X) := \sum_{n \in \mathbb{Z}} \mathrm{Hilb}^{d,n}(X) p^n,$$

where we view the right hand side as a formal Laurent series whose coefficients are elements in the Grothendieck ring of varieties, i.e. $K_0(\mathrm{Var}_{\mathbb{C}})((p))$.

Convention 3.1. *When an index is replaced by a bullet, we will multiply by the appropriate variable and sum over the index. We regard the result as a formal power (or Laurent) series whose coefficients lie in $K_0(\mathrm{Var}_{\mathbb{C}})$ and we extend operations of the Grothendieck group (addition, multiplication, Euler characteristic) to the series in the obvious way.*

For example

$$\mathrm{Hilb}^{\bullet,\bullet}(X) = \sum_{d=0}^{\infty} \sum_{n \in \mathbb{Z}} \mathrm{Hilb}^{d,n}(X) q^d p^n \in K_0(\mathrm{Var}_{\mathbb{C}})((p))[[q]],$$

so that we can write

$$\widehat{\mathrm{DT}}(X) = e(\mathrm{Hilb}^{\bullet,\bullet}(X)).$$

It is notationally convenient to treat an Euler characteristic weighted by a constructible function as a Lebesgue integral, where the measurable sets are constructible sets, the measurable functions are constructible functions, and the measure of a set is given by its Euler characteristic. In this language we have

$$\widehat{\mathrm{DT}}_{d,n}(X) = \int_{\mathrm{Hilb}^{d,n}(X)} 1 \, de, \quad \mathrm{DT}_{d,n}(X) = \int_{\mathrm{Hilb}^{d,n}(X)} \nu \, de$$

and following the bullet convention we have

$$\widehat{\mathrm{DT}}(X) = \int_{\mathrm{Hilb}^{\bullet,\bullet}(X)} 1 \, de, \quad \mathrm{DT}(X) = \int_{\mathrm{Hilb}^{\bullet,\bullet}(X)} \nu \, de.$$

We will also need notation for subsets of the Hilbert scheme which parameterize those subschemes obtained by adding embedded points and/or zero dimensional components to some fixed Cohen-Macaulay curve.

Definition 4. Let $U \subset X$ be an open set (possibly in the fpqc topology) and let $C \subset U$ be a (not necessarily reduced) Cohen-Macaulay subscheme of dimension 1 which we assume is the restriction of some $\overline{C} \subset X$ to U . We define

$$\mathrm{Hilb}^n(U, C) = \{Z \subset U \text{ such that } C \subset Z \text{ and } I_C/I_Z \text{ has finite length } n\}.$$

Via the inclusion $U \subset X$, $\text{Hilb}^n(U, C)$ can be viewed as a constructible subscheme of $\text{Hilb}(X)$. It parameterizes subschemes which roughly speaking are obtained from C by adding n embedded points and/or zero dimensional components.

3. REDUCTION TO PARTITION THICKENED COMB CURVES

The action of \mathbb{C}^* on the fibers of X lifts to the moduli space $\text{Hilb}^{d, \bullet}(X)$. Therefore

$$\int_{\text{Hilb}^{d, \bullet}(X)} 1 \, de = \int_{\text{Hilb}^{d, \bullet}(X)^{\mathbb{C}^*}} 1 \, de.$$

The main result of this section is a classification of the subschemes parameterized by $\text{Hilb}^{d, n}(X)^{\mathbb{C}^*}$, namely the \mathbb{C}^* -invariant subschemes. We find that the maximal Cohen-Macaulay subscheme of a \mathbb{C}^* -invariant subscheme is determined by a point in $\text{Sym}^d(B)$ along with some discrete data (a collection of integer partitions). We begin with some notation.

Definition 5. Let $T = \text{Tot}(K_S|_B)$ and let $p : X \rightarrow T$ be the elliptic fibration induced by the elliptic fibration $p : S \rightarrow B$. We say that a subscheme $C \subset X$ is a **comb curve** if $C = B \cup p^{-1}(Z)$ where $Z \subset T$ is a zero dimensional subscheme which is set-theoretically supported on B .

Let $\lambda = (\lambda_1 \geq \dots \geq \lambda_l)$ be an integer partition. Then λ determines a zero dimensional subscheme $Z_\lambda \subset \text{Spec } \mathbb{C}[[r, s]]$ given by the monomial ideal

$$(1) \quad I_\lambda = (r^{\lambda_1}, r^{\lambda_2} s, \dots, r^{\lambda_l} s^{l-1}, s^l).$$

In terms of λ as a Young diagram, we note $(\rho, \sigma) \in \lambda$ if and only if $r^\rho s^\sigma \notin I_\lambda$.

Definition 6. Let $C = B \cup p^{-1}(Z)$ be a comb curve, let $x_1, \dots, x_n \in B \subset T$ be the points where Z is supported, and let (r_i, s_i) be formal local coordinates on T about each point x_i so that s_i vanishes on $S \cap T$ and r_i vanishes on $R_i \cap T$ where $R_i = \text{Tot}(K_S|_{F_{x_i}})$. We say that C is a **partition thickened comb curve** if there exists partitions $\lambda^{(1)}, \dots, \lambda^{(n)}$ such that Z is given by $Z_{\lambda^{(i)}}$ in the local coordinates (r_i, s_i) about x_i . We denote such a curve by $B \cup_i (\lambda^{(i)} F_{x_i})$.³ We say that a subscheme $Z \subset X$ is a **partition thickened comb curve with points (PCP)** if the maximal Cohen-Macaulay subscheme $Z_{\text{CM}} \subset Z$ is a partition thickened comb curve, in other words,

³Specifically, writing $r := r_i$, $s := s_i$, $\lambda = (\lambda_1 \geq \dots \geq \lambda_l) := \lambda^{(i)}$, $x := x_i$, $F := F_{x_i}$, and t for a coordinate at x vanishing on T , the ideal of $B \cup \lambda F$ in a formal neighbourhood of x is given by $(s, t) \cdot (r^{\lambda_1}, r^{\lambda_2} s, \dots, r^{\lambda_l} s^{l-1}, s^l) \subset \mathbb{C}[[r, s, t]]$.

FIGURE 1. A partition thickened comb curve

$$C = B \cup_i (\lambda^{(i)} F_{x_i}) \cup_j (\mu^{(j)} F_{y_j}).$$

Z is obtained from a partition thickened comb curve by adding embedded points and/or zero dimensional components. We denote by

$$\mathrm{Hilb}_{\mathrm{PCP}}^{d,n}(X) \subset \mathrm{Hilb}^{d,n}(X)$$

the locus in the Hilbert scheme parameterizing partition thickened comb curves with points.

In the next section it will be important to notationally distinguish between singular and smooth fibers. See Figure 1 for an illustration of a partition thickened comb curve with smooth fibers $\{F_{x_i}\}$ thickened by partitions $\{\lambda^{(i)}\}$ and nodal fibers $\{F_{y_j}\}$ thickened by partitions $\{\mu^{(j)}\}$.

Crucially, any effective divisor on S in class $[B + dF]$ is a comb curve, i.e. the scheme theoretic union of B (our chosen section) and some (possibly thickened) fibres with total multiplicity d . This is proved in Lemma 28. The main result of this section is the following:

Theorem 7. *If a subscheme $Z \subset X$ in the class $[Z] = B + dF$ is \mathbb{C}^* -invariant, then it is a partition thickened comb curve with points. That is*

$$\mathrm{Hilb}^{d,n}(X)^{\mathbb{C}^*} \subset \mathrm{Hilb}_{\mathrm{PCP}}^{d,n}(X) \subset \mathrm{Hilb}^{d,n}(X).$$

Moreover, \mathbb{C}^* acts on $\text{Hilb}_{\text{PCP}}^{d,n}(X)$ and there exists a constructible morphism⁴

$$(2) \quad \rho_d : \text{Hilb}_{\text{PCP}}^{d,\bullet}(X) \rightarrow \text{Sym}^d(B)$$

such that if $[Z] \in \text{Hilb}_{\text{PCP}}^{d,n}(X)$, where the maximal Cohen-Macaulay subscheme of Z is $B \cup_i (\lambda^{(i)} F_{x_i})$, then

$$\rho_d([Z]) = \sum_i |\lambda^{(i)}| x_i.$$

Proof. We have to prove the following: Let $Z \subset X$ be a \mathbb{C}^* -fixed subscheme in the class $[Z] = B + dF$, then the underlying Cohen-Macaulay support curve C is a partition thickened comb curve. Let $I_C \subset \mathcal{O}_X$ be the ideal sheaf defining C . Pushing forward along the projection $\pi : X = K_S \rightarrow S$ and using the decomposition into \mathbb{C}^* -weight spaces shows that there exist ideal sheaves

$$I_0 \subset \cdots \subset I_{l-1} \subsetneq \mathcal{O}_S$$

such that

$$\pi_* I_C = \bigoplus_{i=0}^{l-1} I_i \otimes K_S^{-i}.$$

This is essentially proved in [11, Sect. 4] (albeit in the PT rather than the DT setting). Each I_i defines a closed subscheme $C_i \subset S$ satisfying

$$S \supsetneq C_0 \supset \cdots \supset C_{l-1},$$

$$\sum_{i=0}^{l-1} [C_i] = B + dF \in H_2(S).$$

Therefore each C_i has dimension ≤ 1 . In fact each $C_i \subset S$ is a Cohen-Macaulay curve, or else C has embedded points. Since a Cohen-Macaulay curve on a surface is Gorenstein, each C_i is an effective divisor.

⁴A constructible morphism is a map which is regular on each piece of a decomposition of its domain into locally closed subsets. Because we work with Euler characteristics and the Grothendieck group, we need only work with constructible morphisms.

By the nesting condition and Lemma 28, we deduce

$$\begin{aligned} C_0 &= B + \sum_{i=1}^n \lambda_1^{(i)} F_{x_i}, \\ C_1 &= \sum_{i=1}^n \lambda_2^{(i)} F_{x_i}, \\ &\vdots \\ C_{l-1} &= \sum_{i=1}^n \lambda_l^{(i)} F_{x_i}, \end{aligned}$$

for some distinct points $x_1, \dots, x_n \in B$ and $\lambda_1^{(i)} \geq \dots \geq \lambda_l^{(i)}$. This proves that the \mathbb{C}^* -fixed locus lies inside the PCP locus.

Since the \mathbb{C}^* -invariant Cohen-Macaulay curves just described are exactly the support curves of PCP curves, it follows that the PCP locus is \mathbb{C}^* -invariant. Finally, since the assignment $Z \mapsto Z_{\text{CM}}$ which takes a 1-dimensional subscheme to its maximal Cohen-Macaulay subscheme defines a constructible morphism $\text{Hilb}(X) \rightarrow \text{Hilb}(X)$, its restriction to $\text{Hilb}_{\text{PCP}}^{d, \bullet}(X)$ is also constructible and thus gives the constructible morphism ρ_d . \square

4. PUSH-FORWARD TO THE SYMMETRIC PRODUCT

From the \mathbb{C}^* -equivariant inclusions in Theorem 7 and \mathbb{C}^* -localization of Euler characteristic, we have

$$\widehat{\text{DT}}(X) = \int_{\text{Hilb}^{\bullet, \bullet}(X)} 1 \, de = \int_{\text{Hilb}^{\bullet, \bullet}(X)^{\mathbb{C}^*}} 1 \, de = \int_{\text{Hilb}_{\text{PCP}}^{\bullet, \bullet}(X)} 1 \, de.$$

We compute these Euler characteristics by pushing forward along the map ρ_d constructed in Theorem 7. That is we use

$$\int_{\text{Hilb}_{\text{PCP}}^{d, \bullet}(X)} 1 \, de = \int_{\text{Sym}^d(B)} (\rho_d)_*(1) \, de,$$

where $(\rho_d)_*(1)$ is the $\mathbb{Z}((p))$ -valued constructible function on $\text{Sym}^d(B)$ given by pushing forward the Euler characteristic measure [12]. We denote $(\rho_d)_*(1)$ by f_d so by definition, the value of f_d at a point $\mathbf{ax} = \sum_i a_i x_i \in \text{Sym}^d(B)$ is

$$f_d(\mathbf{ax}) = \int_{\rho_d^{-1}(\mathbf{ax})} 1 \, de.$$

We will show that f_d has some nice multiplicative properties. Let $B^{\text{sing}} \subset B$ be the points over which the fibers of $S \rightarrow B$ are singular. Note that $\#B^{\text{sing}} = e(S)$. Let $B^{\text{sm}} = B - B^{\text{sing}}$.

Proposition 8. *Let $x_1, \dots, x_n \in B^{\text{sm}}$ and $y_1, \dots, y_m \in B^{\text{sing}}$ and let $a_1, \dots, a_n, b_1, \dots, b_m$ be positive integers summing to d . Let \mathbf{ax} and \mathbf{by} denote $\sum_i a_i x_i$ and $\sum_j b_j y_j$ respectively. Then there exist $F_1 \in p^{\frac{1}{2}}\mathbb{Z}[[p]]$, $F_2 \in \mathbb{Z}[[p]]$, and $g, h : \mathbb{N} \rightarrow \mathbb{Z}((p))$ such that*

$$f_d(\mathbf{ax} + \mathbf{by}) = F_1^{e(B)} \cdot F_2^{e(S)} \cdot G(\mathbf{ax}) \cdot H(\mathbf{by}),$$

where

$$G(\mathbf{ax}) = \prod_{i=1}^n g(a_i), \quad H(\mathbf{by}) = \prod_{j=1}^m h(b_j).$$

This proposition follows from Proposition 13 which will be stated and proved in the next section.

Corollary 9.

$$\widehat{\text{DT}}(X) = F_1^{e(B)} \cdot F_2^{e(S)} \cdot \left(\sum_{a=0}^{\infty} g(a) q^a \right)^{e(B)-e(S)} \cdot \left(\sum_{b=0}^{\infty} h(b) q^b \right)^{e(S)},$$

where we have set $g(0) = h(0) = 1$.

Proof. We apply Proposition 8 to the computation of $\widehat{\text{DT}}(X)$ as follows

$$\begin{aligned} \widehat{\text{DT}}(X) &= \int_{\text{Hilb}_{\text{PCP}}^{\bullet, \bullet}(X)} 1 \, de \\ &= \int_{\text{Sym}^{\bullet}(B)} f_{\bullet} \, de \\ &= F_1^{e(B)} \cdot F_2^{e(S)} \cdot \int_{\text{Sym}^{\bullet}(B^{\text{sm}})} G \, de \cdot \int_{\text{Sym}^{\bullet}(B^{\text{sing}})} H \, de. \end{aligned}$$

Applying Lemma 29 to this last equation yields the corollary. \square

To prove Proposition 8 and explicitly compute F_1, F_2, g , and h , we need a good understanding of the strata $\rho_d^{-1}(\mathbf{ax} + \mathbf{by}) \subset \text{Hilb}_{\text{PCP}}^{d, \bullet}(X)$.

We define $\Sigma^{\bullet}(\mathbf{x}, \mathbf{y}, \boldsymbol{\lambda}, \boldsymbol{\mu})$ to be the locus of points $Z \in \text{Hilb}_{\text{PCP}}^{d, \bullet}(X)$, for which the maximal Cohen-Macaulay subcurve $Z_{\text{CM}} \subset Z$ is given by

$$C = B \bigcup_{i=1}^n (\lambda^{(i)} F_{x_i}) \bigcup_{j=1}^m (\mu^{(j)} F_{y_j}).$$

The bullet reminds us that we are multiplying by $p^{\chi(\mathcal{O}_Z)}$ and summing over all possible holomorphic Euler characteristics (recall Convention 3.1). We regard $\Sigma^{\bullet}(\mathbf{x}, \mathbf{y}, \boldsymbol{\lambda}, \boldsymbol{\mu})$ as an element in $K_0(\text{Var}_{\mathbb{C}})((p))$.

Theorem 7 gives the following decomposition of the fibers of ρ_d :

$$(3) \quad \rho_d^{-1}(\mathbf{ax} + \mathbf{by}) = \bigsqcup_{\lambda \vdash \mathbf{a}} \bigsqcup_{\mu \vdash \mathbf{b}} \Sigma^\bullet(\mathbf{x}, \mathbf{y}, \lambda, \mu),$$

where

$$\begin{aligned} \mathbf{a} &= (a_1, \dots, a_n), & \mathbf{b} &= (b_1, \dots, b_m), \\ \mathbf{x} &= (x_1, \dots, x_n), & \mathbf{y} &= (y_1, \dots, y_m), \\ \lambda &= (\lambda^{(1)}, \dots, \lambda^{(n)}), & \mu &= (\mu^{(1)}, \dots, \mu^{(m)}), \end{aligned}$$

and the meaning of $\lambda \vdash \mathbf{a}$ and $\mu \vdash \mathbf{b}$ is that $\lambda^{(i)} \vdash a_i$ and $\mu^{(j)} \vdash b_j$ for all i and j .

In the next section, we will see that the Euler characteristic of $\Sigma^\bullet(\mathbf{x}, \mathbf{y}, \lambda, \mu)$ does not depend on the exact location of the points $x_i \in B^{\text{sm}}$ and $y_j \in B^{\text{sing}}$, but only on their number n and m and the partitions $\lambda^{(i)}$ and $\mu^{(j)}$.

5. RESTRICTION TO FORMAL NEIGHBORHOODS

In the previous two sections we reduced our consideration to the strata $\Sigma^\bullet(\mathbf{x}, \mathbf{y}, \lambda, \mu)$ of $\text{Hilb}_{\text{PCP}}^{d, \bullet}(X)$ which parameterize subschemes Z whose maximal Cohen-Macaulay subscheme $Z_{\text{CM}} \subset Z$ is the partition thickened comb curve

$$C = B \cup_i (\lambda^{(i)} F_{x_i}) \cup_j (\mu^{(j)} F_{y_j}).$$

In this section we use an fpqc open cover to express $\Sigma^\bullet(\mathbf{x}, \mathbf{y}, \lambda, \mu)$ as a product of “local” Hilbert schemes. We then use this product to compute the Euler characteristic of $\Sigma^\bullet(\mathbf{x}, \mathbf{y}, \lambda, \mu)$. The main result of this section is Proposition 13.

5.1. The fpqc cover.

The reduced support of C is $B \cup_i F_{x_i} \cup_j F_{y_j}$ which is a nodal curve with nodes at (x_1, \dots, x_n) , (y_1, \dots, y_m) and (z_1, \dots, z_m) where z_j is the node of the nodal fiber F_{y_j} (see Figure 1).

We wish to make an open cover of X which is compatible with the support of C . Intuitively, one can think of the complex analytic open cover consisting of small balls around each of the points $\{x_i, y_j, z_j\}$, a small tubular neighborhood of $B - \{x_i, y_j\}$, small tubular neighborhoods of $F_{x_i} - \{x_i\}$ and $F_{y_j} - \{y_j, z_j\}$, and finally the complement of C .

To work algebraically, we use formal neighborhoods instead of tubular neighborhoods and balls. This has an additional advantage over an analytic cover: the intersection of these open sets is very small in the sense that no embedded points or zero dimensional components can occur inside the intersections of distinct open sets in the cover.

An fpqc cover of a scheme T consists of a collection of flat morphisms $\{\phi_i : T_i \rightarrow T\}_{i \in I}$, which are jointly surjective and satisfy a quasi-compactness condition. See [18, Tag 03NV, Def. 54.15.1] (or [20, Def. 2.34]). Just like for Zariski covers of T , one can glue quasi-coherent sheaves along an fpqc cover. This is known as *fpqc descent* [18, Tag 023R, Prop. 34.5.2] (or [20, Thm. 4.23]). The type of fpqc covers we are interested in arise from taking the formal neighborhood of a closed subscheme $Z \subset T$ and its complement $U = T \setminus Z$ much like [18, Tag, 03NV, Ex. 54.15.3(5)]. More specifically:

Definition 10. We define \mathfrak{U} , a cover of X , to be the collection of the following sets, open in the fpqc topology:

- (1) W , the complement of the support of C .
- (2) \widehat{X}_{x_i} , for $i = 1, \dots, n$, the formal neighborhoods of the points x_i .
- (3) \widehat{X}_{y_j} , for $j = 1, \dots, m$, the formal neighborhoods of the points y_j .
- (4) \widehat{X}_{z_j} , for $j = 1, \dots, m$, the formal neighborhoods of the points z_j .
- (5) \widehat{X}_{B° , the formal neighborhood of $B^\circ \subset X$ where $B^\circ = B - \{x_1, \dots, x_n, y_1, \dots, y_m\}$.
- (6) $\widehat{X}_{F_{x_i}^\circ}$, for $i = 1, \dots, n$ the formal neighborhood of $F_{x_i}^\circ \subset X$ where

$$F_{x_i}^\circ = F_{x_i} - \{x_i\}.$$

- (7) $\widehat{X}_{F_{y_j}^\circ}$, for $j = 1, \dots, m$ the formal neighborhood of $F_{y_j}^\circ \subset X$ where

$$F_{y_j}^\circ = F_{y_j} - \{y_j, z_j\}.$$

The subschemes B° , $F_{x_i}^\circ$, and $F_{y_j}^\circ$ are not closed in X but they are locally closed. To define \widehat{X}_{V° , the formal neighborhood of a locally closed subscheme V° , we take any open $X^\circ \subset X$ such that $V^\circ \subset X^\circ$ is closed and then define \widehat{X}_{V° to be \widehat{X}_{X° .

We consider the formal neighborhoods which are members of the cover \mathfrak{U} not as formal schemes, but as the associated non-finite-type schemes. The scheme maps

$$\widehat{X}_{x_i} \rightarrow X, \quad \widehat{X}_{B^\circ} \rightarrow X, \dots$$

are flat. This follows from the fact that the formal completion \widehat{A} of a noetherian ring A along an ideal $I \subset A$ is A -flat ([18, Tag 0BNH, Lemma 10.96.2] or [1, Prop. 10.14]). Since our maps are jointly surjective, \mathfrak{U} forms an fpqc cover. For $U \in \mathfrak{U}$, we suppress the associated map $U \rightarrow X$ from the notation and use the usual restriction notation to denote the pullback, for example

$$U|_C := U \times_X C.$$

5.2. $\Sigma^\bullet(x, y, \lambda, \mu)$ as a product of local Hilbert schemes.

Let

$$C = B \cup_i (\lambda^{(i)} F_{x_i}) \cup_j (\mu^{(j)} F_{y_j}).$$

Recall that the component

$$\Sigma^\bullet(x, y, \lambda, \mu) \subset \text{Hilb}_{\text{pCP}}^{d, \bullet}(X)$$

parameterizes subschemes $Z \subset X$ whose maximal Cohen-Macaulay subscheme is C , i.e. Z is obtained from C by adding embedded points and/or zero dimensional components. We apply the definition of $\text{Hilb}^n(U, C)$ (Definition 4) to the open sets in our cover \mathfrak{U} . The following lemma writes the stratum $\Sigma^\bullet(x, y, \lambda, \mu)$ as a product of those schemes.

Lemma 11. *The following equation holds in $K_0(\text{Var}_{\mathbb{C}})((p))$*

$$\begin{aligned} \Sigma^\bullet(x, y, \lambda, \mu) &= p^{\chi(\mathcal{O}_C)} \cdot \prod_{U \in \mathfrak{U}} \text{Hilb}^\bullet(U, C|_U) \\ &= p^{\chi(\mathcal{O}_C)} \cdot \text{Hilb}^\bullet(W) \cdot \text{Hilb}^\bullet(\widehat{X}_{B^\circ}, B^\circ) \\ &\quad \cdot \prod_{i=1}^n \text{Hilb}^\bullet(\widehat{X}_{x_i}, \widehat{C}_{x_i}) \cdot \text{Hilb}^\bullet(\widehat{X}_{F_{x_i}^\circ}, \lambda^{(i)} F_{x_i}^\circ) \\ &\quad \cdot \prod_{j=1}^m \text{Hilb}^\bullet(\widehat{X}_{y_j}, \widehat{C}_{y_j}) \cdot \text{Hilb}^\bullet(\widehat{X}_{z_j}, \widehat{C}_{z_j}) \cdot \text{Hilb}^\bullet(\widehat{X}_{F_{y_j}^\circ}, \mu^{(j)} F_{y_j}^\circ) \end{aligned}$$

Note that we have implicitly introduced notation for our curve restricted to the various open sets: $\widehat{C}_{x_i} := C|_{\widehat{X}_{x_i}}$, $\mu^{(j)} F_{y_j}^\circ := C|_{\widehat{X}_{F_{y_j}^\circ}}$, etc.

Proof. Let Z be a subscheme corresponding to a point in $\Sigma^\bullet(x, y, \lambda, \mu)$. Our fpqc cover \mathfrak{U} has the property that every zero dimensional component or embedded point of Z is contained in a unique open set in the cover. In other words, the restriction of Z to any intersection of sets in the cover \mathfrak{U} has no embedded points or zero dimensional components. fpqc descent ([18, Tag 023R, Prop. 34.5.2] or [20, Thm. 4.23]) then tells us that Z is uniquely determined by its restriction to the open sets of the cover and any collection of structure sheaves $\{\mathcal{O}_{Z_U}\}_{U \in \mathfrak{U}}$, such that Z_U has maximal Cohen-Macaulay curve $C|_U$, determines such a structure sheaf. We stress that we only use a very weak version of fpqc descent: since the underlying Cohen-Macaulay curve C is already fixed, restriction of \mathcal{O}_Z to the open subsets of the fpqc cover determines \mathcal{O}_Z and there are no conditions on the overlaps. In other words, we have a constructible bijective morphism from the product of Hilbert schemes on the open sets to the Hilbert scheme on X which induces the equality in the Grothendieck group. Finally, we verify

that the powers of p correctly match up each side. For a subscheme Z with maximal Cohen-Macaulay subscheme C , we have

$$\begin{aligned}\chi(\mathcal{O}_Z) &= \chi(\mathcal{O}_C) + \text{length}(I_C/I_Z) \\ &= \chi(\mathcal{O}_C) + \sum_{U \in \mathfrak{U}} \text{length}(I_C/I_Z|_U).\end{aligned}$$

Therefore the $p^{\chi(\mathcal{O}_Z)}$ term on the left hand side of the equation correctly matches the

$$p^{\chi(\mathcal{O}_C)} \cdot \prod_{U \in \mathfrak{U}} p^{\text{length}(I_C/I_Z|_U)}$$

term on the right hand side. \square

Lemma 12. *Let*

$$C = B \cup_i (\lambda^{(i)} F_{x_i}) \cup_j (\mu^{(j)} F_{y_j}),$$

then

$$\chi(\mathcal{O}_C) = \chi(\mathcal{O}_B) - \sum_{i=1}^n \lambda_1^{(i)} - \sum_{j=1}^m \mu_1^{(j)}.$$

Proof. Since $\lambda^{(i)} F_{x_i} = p^{-1}(Z_{\lambda^{(i)}})$ and p is an elliptic fibration, $\chi(\mathcal{O}_{F_{x_i}}) = 0$ and similarly we have $\chi(\mathcal{O}_{F_{y_j}}) = 0$. Note that $B \cap \lambda^{(i)} F_{x_i}$ and $B \cap \mu^{(j)} F_{y_j}$ are zero dimensional subschemes of length $\lambda_1^{(i)}$ and $\mu_1^{(j)}$ respectively (c.f. equation (1)). The lemma then follows from the exact sequence

$$0 \rightarrow \mathcal{O}_C \rightarrow \mathcal{O}_B \oplus_i \mathcal{O}_{\lambda^{(i)} F_{x_i}} \oplus_j \mathcal{O}_{\mu^{(j)} F_{y_j}} \rightarrow \oplus_i \mathcal{O}_{B \cap \lambda^{(i)} F_{x_i}} \oplus_j \mathcal{O}_{B \cap \mu^{(j)} F_{y_j}} \rightarrow 0.$$

\square

5.3. Formal coordinates and Hilbert schemes of $\text{Spec } \mathbb{C}[[r, s, t]]$.

Let λ, μ, ν be integer partitions which we also regard as subsets in $(\mathbb{Z}_{\geq 0})^2$ by their diagram as in [6]. Consider the subscheme

$$Z_{\lambda\mu\nu} = Z_{\lambda\emptyset\emptyset} \cup Z_{\emptyset\mu\emptyset} \cup Z_{\emptyset\emptyset\nu} \subset \mathbb{C}^3 = \text{Spec } \mathbb{C}[r, s, t]$$

defined by the monomial ideal

$$I_{\lambda\mu\nu} = I_{\lambda\emptyset\emptyset} \cap I_{\emptyset\mu\emptyset} \cap I_{\emptyset\emptyset\nu},$$

where

$$\begin{aligned}r^\rho s^\sigma t^\tau \in I_{\lambda\emptyset\emptyset} &\iff (\sigma, \tau) \notin \lambda, \\ r^\rho s^\sigma t^\tau \in I_{\emptyset\mu\emptyset} &\iff (\tau, \rho) \notin \mu, \\ r^\rho s^\sigma t^\tau \in I_{\emptyset\emptyset\nu} &\iff (\rho, \sigma) \notin \nu.\end{aligned}$$

Let $\widehat{Z}_{\lambda\mu\nu}$ be the restriction of $Z_{\lambda\mu\nu}$ to $\widehat{\mathbb{C}}_0^3 = \text{Spec } \mathbb{C}[[r, s, t]]$. Let

$$(4) \quad \text{Hilb}^n(\lambda, \mu, \nu) := \text{Hilb}^n(\widehat{\mathbb{C}}_0^3, \widehat{Z}_{\lambda\mu\nu})$$

be the Hilbert scheme parameterizing the subschemes obtained by adding a length n embedded point to $Z_{\lambda\mu\nu}$ at the origin (see Definition 4). We emphasize that the subschemes parameterized by $\text{Hilb}^n(\lambda, \mu, \nu)$ need not be monomial — the embedded points at the origin have no restrictions.

We note that the permutations $(r, s, t) \mapsto (t, r, s)$ and $(r, s, t) \mapsto (s, r, t)$ induce the isomorphisms

$$\text{Hilb}^n(\lambda, \mu, \nu) \cong \text{Hilb}^n(\nu, \lambda, \mu), \quad \text{Hilb}^n(\lambda, \mu, \nu) \cong \text{Hilb}^n(\mu', \lambda', \nu'),$$

where $\lambda' = \{(i, j) : (j, i) \in \lambda\}$ denotes conjugate partition.

We define $\mathbf{V}_{\lambda\mu\nu} \in \mathbb{Z}[[p]]$ by

$$\tilde{\mathbf{V}}_{\lambda\mu\nu} = e(\text{Hilb}^\bullet(\lambda, \mu, \nu))$$

and note the symmetries

$$\tilde{\mathbf{V}}_{\lambda\mu\nu} = \tilde{\mathbf{V}}_{\nu\lambda\mu} = \tilde{\mathbf{V}}_{\mu'\lambda'\nu'}.$$

We now choose formal local coordinates at x_i , y_j , and z_j so that we can identify $\text{Hilb}^n(\hat{X}_{x_i}, \hat{C}_{x_i})$, $\text{Hilb}^n(\hat{X}_{y_j}, \hat{C}_{y_j})$, and $\text{Hilb}^n(\hat{X}_{z_j}, \hat{C}_{z_j})$ in terms of $\text{Hilb}^n(\lambda, \mu, \nu)$ for appropriate choices of λ, μ, ν .

Recall that $S \subset X$ is the elliptic surface and $T = \text{Tot}(K_S|_B)$. For any point $p \in B$, let $R_p = \text{Tot}(K_S|_{F_p})$. We choose isomorphisms

$$\hat{X}_{x_i} \cong \hat{X}_{y_j} \cong \hat{X}_{z_j} \cong \text{Spec } \mathbb{C}[[r, s, t]]$$

such that on \hat{X}_p when p is x_i or y_j

$$R_p = \{r = 0\}, \quad S = \{s = 0\}, \quad T = \{t = 0\}$$

and when p is z_j

$$R_p = \{rt = 0\}, \quad S = \{s = 0\}.$$

Note that at x_i or y_j , the curve B is given by $\{s = t = 0\}$ and the fiber F_{x_i} or F_{y_j} is given by $\{s = r = 0\}$. At the point z_j , the fiber is a nodal curve and is given by $\{s = rt = 0\}$.

With these choices, we have the identifications

$$\begin{aligned} \text{Hilb}^n(\hat{X}_{x_i}, \hat{C}_{x_i}) &\cong \text{Hilb}^n(\square, \emptyset, \lambda^{(i)}), \\ \text{Hilb}^n(\hat{X}_{y_j}, \hat{C}_{y_j}) &\cong \text{Hilb}^n(\square, \emptyset, \mu^{(j)}), \\ \text{Hilb}^n(\hat{X}_{z_j}, \hat{C}_{z_j}) &\cong \text{Hilb}^n(\mu^{(j)'}, \emptyset, \mu^{(j)}). \end{aligned}$$

Here \square is the unique partition of size 1 (whose diagram is a single box), \emptyset is the empty partition. Recall that the elements of the Hilbert schemes on the RHS of the above do not need to be monomial ideals: although their underlying maximal Cohen-Macaulay subscheme is monomial, they may have arbitrary embedded points at the origin.

An immediate consequence of the above and the symmetries of \tilde{V} is

$$(5) \quad \begin{aligned} e \left(\text{Hilb}^\bullet \left(\hat{X}_{x_i}, \hat{C}_{x_i} \right) \right) &= \tilde{V}_{\lambda^{(i)} \square \emptyset}, \\ e \left(\text{Hilb}^\bullet \left(\hat{X}_{y_j}, \hat{C}_{y_j} \right) \right) &= \tilde{V}_{\mu^{(j)} \square \emptyset}, \\ e \left(\text{Hilb}^\bullet \left(\hat{X}_{z_j}, \hat{C}_{z_j} \right) \right) &= \tilde{V}_{\mu^{(j)} \mu^{(j)'} \emptyset}. \end{aligned}$$

We also choose formal local coordinates at all other points. For each point in B° , choose local coordinates (r, s, t) such that $T = \{t = 0\}$ and $S = \{s = 0\}$. For each point in $F_{x_i}^\circ$ or $F_{y_j}^\circ$, choose local coordinates (r, s, t) such that $S = \{s = 0\}$ and $R_{x_i} = \{r = 0\}$ or $R_{y_j} = \{r = 0\}$ respectively. For each point in W , choose any formal local coordinates (r, s, t) .

Consider the following constructible “support” morphisms

$$\begin{aligned} \sigma_W &: \text{Hilb}^\bullet(W) \rightarrow \text{Sym}^\bullet(W), \\ \sigma_{B^\circ} &: \text{Hilb}^\bullet(\hat{X}_{B^\circ}, B^\circ) \rightarrow \text{Sym}^\bullet(B^\circ) \\ \sigma_{F_{x_i}^\circ} &: \text{Hilb}^\bullet(\hat{X}_{F_{x_i}^\circ}, \lambda^{(i)} F_{x_i}^\circ) \rightarrow \text{Sym}^\bullet(F_{x_i}^\circ), \\ \sigma_{F_{y_j}^\circ} &: \text{Hilb}^\bullet(\hat{X}_{F_{y_j}^\circ}, \mu^{(j)} F_{y_j}^\circ) \rightarrow \text{Sym}^\bullet(F_{y_j}^\circ), \end{aligned}$$

which to each subscheme Z representing a point in a Hilbert scheme associates the location and length of the embedded points or zero dimensional components of Z .

Consider a point p in W , B° , $F_{x_i}^\circ$, or $F_{y_j}^\circ$. Then using the formal local coordinates chosen above, we see that

$$\begin{aligned} \sigma_W^{-1}(np) &\cong \text{Hilb}^n(\emptyset, \emptyset, \emptyset), \\ \sigma_{B^\circ}^{-1}(np) &\cong \text{Hilb}^n(\square, \emptyset, \emptyset), \\ \sigma_{F_{x_i}^\circ}^{-1}(np) &\cong \text{Hilb}^n(\emptyset, \emptyset, \lambda^{(i)}), \\ \sigma_{F_{y_j}^\circ}^{-1}(np) &\cong \text{Hilb}^n(\emptyset, \emptyset, \mu^{(j)}). \end{aligned}$$

Moreover, the pre-images of the support morphisms clearly satisfy the following multiplicative property

$$\sigma_U^{-1} \left(\sum_i n_i p_i \right) = \prod_i \sigma_U^{-1}(n_i p_i).$$

Pushing forward the Euler characteristic measure along the support maps, applying Lemma 29, and using the symmetries of \tilde{V} we find the following formulas

$$\begin{aligned}
(6) \quad e(\mathrm{Hilb}^\bullet(W)) &= \int_{\mathrm{Sym}^\bullet(W)} (\sigma_W)_* (1) de = \left(\widetilde{V}_{\emptyset\emptyset\emptyset} \right)^{e(W)} \\
e\left(\mathrm{Hilb}^\bullet\left(\widehat{X}_{B^\circ}, B^\circ\right)\right) &= \int_{\mathrm{Sym}^\bullet(B^\circ)} (\sigma_{B^\circ})_* (1) de = \left(\widetilde{V}_{\square\emptyset\emptyset} \right)^{e(B^\circ)} \\
e\left(\mathrm{Hilb}^\bullet\left(\widehat{X}_{F_{x_i}^\circ}, \lambda^{(i)} F_{x_i}^\circ\right)\right) &= \int_{\mathrm{Sym}^\bullet(F_{x_i}^\circ)} \left(\sigma_{F_{x_i}^\circ} \right)_* (1) de = \left(\widetilde{V}_{\lambda^{(i)}\emptyset\emptyset} \right)^{e(F_{x_i}^\circ)} \\
e\left(\mathrm{Hilb}^\bullet\left(\widehat{X}_{F_{y_j}^\circ}, \mu^{(j)} F_{y_j}^\circ\right)\right) &= \int_{\mathrm{Sym}^\bullet(F_{y_j}^\circ)} \left(\sigma_{F_{y_j}^\circ} \right)_* (1) de = \left(\widetilde{V}_{\mu^{(j)}\emptyset\emptyset} \right)^{e(F_{y_j}^\circ)}
\end{aligned}$$

We are now ready to prove the main result of this section:

Proposition 13. *Recall that $f_d = (\rho_d)_* (1) \in \mathbb{Z}((p))$ is the push forward of the Euler characteristic measure by the map ρ_d . As before, let $x_1, \dots, x_n \in B^{\mathrm{sm}}$, $y_1, \dots, y_m \in B^{\mathrm{sing}}$ and let $a_1, \dots, a_n, b_1, \dots, b_m$ be positive integers summing to d . Then*

$$f_d(\mathbf{ax} + \mathbf{by}) = \left(p^{\frac{1}{2}} \frac{\widetilde{V}_{\square\emptyset\emptyset}}{\widetilde{V}_{\emptyset\emptyset\emptyset}} \right)^{e(B)} \cdot \widetilde{V}_{\emptyset\emptyset\emptyset}^{e(S)} \cdot \prod_{i=1}^n g(a_i) \prod_{j=1}^m h(b_j),$$

where

$$\begin{aligned}
g(a) &= \sum_{\lambda \vdash a} p^{-\lambda_1} \frac{\widetilde{V}_{\emptyset\emptyset\emptyset} \widetilde{V}_{\lambda\square\emptyset}}{\widetilde{V}_{\square\emptyset\emptyset} \widetilde{V}_{\lambda\emptyset\emptyset}}, \\
h(b) &= \sum_{\mu \vdash b} p^{-\mu_1} \frac{\widetilde{V}_{\mu\mu'\emptyset} \widetilde{V}_{\mu\square\emptyset}}{\widetilde{V}_{\square\emptyset\emptyset} \widetilde{V}_{\mu\emptyset\emptyset}}.
\end{aligned}$$

Note that this proves Proposition 8 and provides the values of the unknowns g, h (as above) and F_1, F_2

$$F_1 = p^{\frac{1}{2}} \frac{\widetilde{V}_{\square\emptyset\emptyset}}{\widetilde{V}_{\emptyset\emptyset\emptyset}}, \quad F_2 = \widetilde{V}_{\emptyset\emptyset\emptyset}.$$

Proof. We apply, in order, equation (3), Lemma 11, equations (5) and (6), and Lemma 12 to compute

$$\begin{aligned}
f_d(\mathbf{ax} + \mathbf{by}) &= e(\rho_d^{-1}(\mathbf{ax} + \mathbf{by})) \\
&= \sum_{\lambda \vdash \mathbf{a}} \sum_{\mu \vdash \mathbf{b}} e(\Sigma^\bullet(\mathbf{x}, \mathbf{y}, \lambda, \mu)) \\
&= p^{\chi(\mathcal{O}_C)} \cdot e(\text{Hilb}^\bullet(W)) \cdot e\left(\text{Hilb}^\bullet(\widehat{X}_{B^\circ}, B^\circ)\right) \cdot \sum_{\lambda \vdash \mathbf{a}} \sum_{\mu \vdash \mathbf{b}} \\
&\quad \cdot \prod_{i=1}^n e\left(\text{Hilb}^\bullet(\widehat{X}_{x_i}, \widehat{C}_{x_i})\right) \cdot e\left(\text{Hilb}^\bullet(\widehat{X}_{F_{x_i}^\circ}, \lambda^{(i)} F_{x_i}^\circ)\right) \\
&\quad \cdot \prod_{j=1}^m e\left(\text{Hilb}^\bullet(\widehat{X}_{y_j}, \widehat{C}_{y_j})\right) \cdot e\left(\text{Hilb}^\bullet(\widehat{X}_{z_j}, \widehat{C}_{z_j})\right) \cdot e\left(\text{Hilb}^\bullet(\widehat{X}_{F_{y_j}^\circ}, \mu^{(j)} F_{y_j}^\circ)\right) \\
&= p^{\chi(\mathcal{O}_C)} \cdot \widetilde{V}_{\emptyset\emptyset\emptyset}^{e(W)} \cdot \widetilde{V}_{\square\emptyset\emptyset}^{e(B^\circ)} \cdot \sum_{\lambda \vdash \mathbf{a}} \sum_{\mu \vdash \mathbf{b}} \\
&\quad \cdot \prod_{i=1}^n \widetilde{V}_{\lambda^{(i)}\square\emptyset} \cdot \widetilde{V}_{\lambda^{(i)}\emptyset\emptyset}^{e(F_{x_i}^\circ)} \cdot \prod_{j=1}^m \widetilde{V}_{\mu^{(j)}\square\emptyset} \cdot \widetilde{V}_{\mu^{(j)}\mu^{(j)'}\emptyset} \cdot \widetilde{V}_{\mu^{(j)}\emptyset\emptyset}^{e(F_{y_j}^\circ)} \\
&= p^{\chi(\mathcal{O}_B)} \cdot \widetilde{V}_{\emptyset\emptyset\emptyset}^{e(W)} \cdot \widetilde{V}_{\square\emptyset\emptyset}^{e(B^\circ)} \\
&\quad \cdot \prod_{i=1}^n \sum_{\lambda^{(i)} \vdash a_i} p^{-\lambda_1^{(i)}} \widetilde{V}_{\lambda^{(i)}\square\emptyset} \cdot \widetilde{V}_{\lambda^{(i)}\emptyset\emptyset}^{e(F_{x_i}^\circ)} \\
&\quad \cdot \prod_{j=1}^m \sum_{\mu^{(j)} \vdash b_j} p^{-\mu_1^{(j)}} \widetilde{V}_{\mu^{(j)}\square\emptyset} \cdot \widetilde{V}_{\mu^{(j)}\mu^{(j)'}\emptyset} \cdot \widetilde{V}_{\mu^{(j)}\emptyset\emptyset}^{e(F_{y_j}^\circ)}.
\end{aligned}$$

We note that $e(F_{x_i}) = 0$ and $e(F_{y_j}) = 1$ so that $e(F_{x_i}^\circ) = -1$ and $e(F_{y_j}^\circ) = -1$. Also, since $e(B^\circ) = e(B) - n - m$, we have

$$\begin{aligned}
e(W) &= e(S) - e(B^\circ) - \sum_i e(F_{x_i}) - \sum_j e(F_{y_j}) \\
&= e(S) - e(B) + n.
\end{aligned}$$

The above equations allow us to redistribute the terms of $f_d(\mathbf{ax} + \mathbf{by})$ as follows

$$\begin{aligned} f_d(\mathbf{ax} + \mathbf{by}) &= p^{\chi(\mathcal{O}_B)} \cdot \tilde{V}_{\emptyset\emptyset\emptyset}^{e(S)} \cdot \left(\frac{\tilde{V}_{\square\emptyset\emptyset}}{\tilde{V}_{\emptyset\emptyset\emptyset}} \right)^{e(B)} \\ &\quad \cdot \prod_{i=1}^n \sum_{\lambda^{(i)} \vdash a_i} p^{-\lambda_1^{(i)}} \cdot \frac{\tilde{V}_{\emptyset\emptyset\emptyset} \tilde{V}_{\lambda^{(i)}\square\emptyset}}{\tilde{V}_{\square\emptyset\emptyset} \tilde{V}_{\lambda^{(i)}\emptyset\emptyset}} \\ &\quad \cdot \prod_{j=1}^m \sum_{\mu^{(j)} \vdash b_j} p^{-\mu_1^{(j)}} \cdot \frac{\tilde{V}_{\mu^{(j)}\mu^{(j)'}\emptyset} \tilde{V}_{\mu^{(j)}\square\emptyset}}{\tilde{V}_{\square\emptyset\emptyset} \tilde{V}_{\mu^{(j)}\emptyset\emptyset}}. \end{aligned}$$

Noting that $\chi(\mathcal{O}_B) = e(B)/2$, we see the above proves the proposition. \square

6. REDUCTION TO THE TOPOLOGICAL VERTEX

In this section, we express $\widehat{\text{DT}}(X)$ in terms of the topological vertex, and then use the trace formulas of [6] to obtain a closed formula for $\widehat{\text{DT}}(X)$.

6.1. $\tilde{V}_{\lambda\mu\nu}$ in terms of $V_{\lambda\mu\nu}$.

Recall that the coefficients of the series $\tilde{V}_{\lambda\mu\nu} \in \mathbb{Z}[[p]]$ are given by the Euler characteristics of the local Hilbert schemes

$$\tilde{V}_{\lambda\mu\nu} = e \left(\text{Hilb}^\bullet(\widehat{\mathbb{C}}_0^3, \widehat{Z}_{\lambda\mu\nu}) \right).$$

We can compute the Euler characteristics using the $T = (\mathbb{C}^*)^3$ -action on the Hilbert schemes induced by the T -action on \mathbb{C}^3 . An ideal $I \subset \mathbb{C}[r, s, t]$ is T -invariant if and only if it is generated by monomials. Moreover, there is a bijection between monomial ideals and 3D partitions (see § 6.3 of [6]) where a monomial ideal $I \subset \mathbb{C}[r, s, t]$ corresponds to a 3D partition $\pi \in (\mathbb{Z}_{\geq 0})^3$ by

$$(\rho, \sigma, \tau) \in \pi \iff r^\rho s^\sigma t^\tau \notin I.$$

The subschemes represented by points in $\text{Hilb}^\bullet(\widehat{\mathbb{C}}_0^3, \widehat{Z}_{\lambda\mu\nu})^T$ are given by monomial ideals corresponding to 3D-partitions asymptotic to $(\lambda\mu\nu)$, see [6, Defn 1]. Consequently,

$$\begin{aligned} \tilde{V}_{\lambda\mu\nu} &= e \left(\text{Hilb}^\bullet(\widehat{\mathbb{C}}_0^3, \widehat{Z}_{\lambda\mu\nu})^T \right) \\ &= \sum_{\pi} p^{n(\pi)}, \end{aligned}$$

where the sum runs over all 3D partitions asymptotic to $(\lambda\mu\nu)$ and $n(\pi)$ is the number of boxes in π which are not contained in any of the legs.

We see that $\widetilde{V}_{\lambda\mu\nu}$ differs from the usual topological vertex by an overall normalization

$$V_{\lambda\mu\nu} = p^{|\pi_{\min}|} \widetilde{V}_{\lambda\mu\nu},$$

where $V_{\lambda\mu\nu}$ is the usual topological vertex [6, Defn 2] and $|\pi_{\min}|$ is the renormalized volume [6, page 2] of the minimal 3D partition asymptotic to $(\lambda\mu\nu)$.

Lemma 14. *The following hold*

$$V_{\lambda\emptyset\emptyset} = \widetilde{V}_{\lambda\emptyset\emptyset}, \quad V_{\lambda\Box\emptyset} = p^{-\lambda_1} \widetilde{V}_{\lambda\Box\emptyset}, \quad V_{\mu\mu'\emptyset} = p^{-\|\mu\|^2} \widetilde{V}_{\mu\mu'\emptyset},$$

where $\|\mu\|^2 := \sum_{j=1}^{\infty} \mu_j^2$.

Proof. The renormalized volume of a 3D-partition asymptotic to $(\lambda\mu\nu)$ is defined by

$$|\pi| = \sum_{(\rho,\sigma,\tau) \in \pi} (1 - \# \text{ of legs of } \pi \text{ containing } (\rho, \sigma, \tau)).$$

For π_{\min} , the minimal 3D-partition asymptotic to $(\lambda\Box\emptyset)$, the only cubes contributing to $|\pi_{\min}|$ are those contained in both the \Box -leg and the λ -leg. They intersect exactly in the cubes corresponding to the first part of λ , namely λ_1 . Thus $|\pi_{\min}| = -\lambda_1$ in this case.

For the case of $(\lambda\emptyset\emptyset)$ every cube is in the λ -leg and so $|\pi_{\min}| = 0$. For the case of $(\mu\mu'\emptyset)$, each cube in the intersection of the μ -leg and the μ' -leg contribute -1 and all other cubes contribute 0. This intersection is a stack of squares of side lengths μ_1, μ_2, \dots and hence

$$|\pi_{\min}| = -\sum_{j=1}^{\infty} \mu_j^2. \quad \square$$

6.2. Applying the trace formulas.

Substituting the values of F_1 , F_2 , g , and h from Proposition 13 into Corollary 9, and then substituting in the formulas from Lemma 14 we obtain the following

$$\begin{aligned} \widehat{\text{DT}}(X) &= \left(p^{\frac{1}{2}} \frac{V_{\Box\emptyset\emptyset}}{V_{\emptyset\emptyset\emptyset}} \right)^{e(B)} \cdot V_{\emptyset\emptyset\emptyset}^{e(S)} \cdot \left(\sum_{\lambda} \frac{V_{\emptyset\emptyset\emptyset} V_{\lambda\Box\emptyset}}{V_{\Box\emptyset\emptyset} V_{\lambda\emptyset\emptyset}} q^{|\lambda|} \right)^{e(B)-e(S)} \\ &\quad \cdot \left(\sum_{\mu} p^{\|\mu\|^2} \frac{V_{\mu\mu'\emptyset} V_{\mu\Box\emptyset}}{V_{\Box\emptyset\emptyset} V_{\mu\emptyset\emptyset}} q^{|\mu|} \right)^{e(S)}. \end{aligned}$$

From the Okounkov-Reshitikhin-Vafa formula for the topological vertex [16], [6, eqn 5] we get

$$V_{\emptyset\emptyset\emptyset} = M(p), \quad V_{\square\emptyset\emptyset} = \frac{M(p)}{1-p},$$

which we substitute into the above to find

$$\begin{aligned} \widehat{\text{DT}}(X) &= \left(\frac{1}{p^{-\frac{1}{2}} - p^{\frac{1}{2}}} \right)^{e(B)} \left(\sum_{\lambda} (1-p) \frac{V_{\lambda\square\emptyset}}{V_{\lambda\emptyset\emptyset}} q^{|\lambda|} \right)^{e(B)-e(S)} \\ &\quad \cdot \left(\sum_{\mu} (1-p) p^{\|\mu\|^2} V_{\mu\mu'\emptyset} \frac{V_{\mu\square\emptyset}}{V_{\mu\emptyset\emptyset}} q^{|\mu|} \right)^{e(S)}. \end{aligned}$$

Applying [6, eqns (2)&(4)], we see that

$$\begin{aligned} \widehat{\text{DT}}(X) &= \left(p^{-\frac{1}{2}} - p^{\frac{1}{2}} \right)^{-e(B)} \cdot \left(\prod_{d=1}^{\infty} \frac{(1-q^d)}{(1-pq^d)(1-p^{-1}q^d)} \right)^{e(B)-e(S)} \\ &\quad \cdot \left(M(p) \prod_{d=1}^{\infty} \frac{M(p, q^d)}{(1-pq^d)(1-p^{-1}q^d)} \right)^{e(S)}. \end{aligned}$$

Noting that $e(B)$ is even, the above expression is easily seen to be equivalent to the formula for $\widehat{\text{DT}}(X)$ in Theorem 1. Since the formula for $\widehat{\text{DT}}_{\text{fib}}(X)$ was previously proven by Toda, we may now regard the proof of Theorem 1 complete. In the next section, we will outline the proof of the formula for $\widehat{\text{DT}}_{\text{fib}}(X)$ using our methods.

7. THE CASE OF $\widehat{\text{DT}}_{\text{fib}}(X)$

The formula for $\widehat{\text{DT}}_{\text{fib}}(X)$ given in Theorem 1 follows from a wall-crossing computation of Toda [19, Thm 6.9] along with the PT/DT correspondence [4]. However in this section we describe how to adapt our computation of $\widehat{\text{DT}}(X)$ to the easier case of $\widehat{\text{DT}}_{\text{fib}}(X)$. Our approach yields a proof which is independent of Toda's.

Definition 15. We say that a subscheme $C \subset X$ is a **partition thickened fiber curve** if it is of the form

$$C = \cup_i (\lambda^{(i)} F_{x_i}),$$

where we are using the notation of Definition 6. We say that a subscheme $Z \subset X$ is a **partition thickened fiber curve with points (PFP)** if the

maximal Cohen-Macaulay subscheme $Z_{\text{CM}} \subset Z$ is a partition thickened fiber curve. We denote by

$$\text{Hilb}_{\text{PFP}}^{dF,n}(X) \subset \text{Hilb}^{dF,n}(X)$$

the locus in the Hilbert scheme parameterizing partition thickened fiber curves with points.

Our proof of Theorem 7 is easily adapted to prove the following:

Theorem 16. *If a subscheme $Z \subset X$ in the class $[Z] = dF$ is \mathbb{C}^* -invariant, then it is a partition thickened fiber curve with points. That is*

$$\text{Hilb}^{dF,n}(X)^{\mathbb{C}^*} \subset \text{Hilb}_{\text{PFP}}^{dF,n}(X) \subset \text{Hilb}^{dF,n}(X).$$

Moreover, \mathbb{C}^* acts on $\text{Hilb}_{\text{PFP}}^{dF,n}(X)$ and there exists a morphism

$$\rho_d^{\text{fib}} : \text{Hilb}_{\text{PFP}}^{dF,\bullet}(X) \rightarrow \text{Sym}^d(B)$$

such that if $[Z] \in \text{Hilb}_{\text{PFP}}^{dF,n}(X)$, where the maximal Cohen-Macaulay subscheme of Z is $\cup_i (\lambda^{(i)} F_{x_i})$, then

$$\rho_d^{\text{fib}}([Z]) = \sum_i |\lambda^{(i)}| x_i.$$

It follows that the pre-images of points under the map ρ_d^{fib} break into components

$$(\rho_d^{\text{fib}})^{-1}(\mathbf{ax} + \mathbf{by}) = \bigsqcup_{\lambda \vdash \mathbf{a}} \bigsqcup_{\mu \vdash \mathbf{b}} \Sigma_{\text{fib}}^{\bullet}(\mathbf{x}, \mathbf{y}, \lambda, \mu),$$

where we have adopted the same notation as in Section 4. Note that the strata

$$\Sigma_{\text{fib}}^{\bullet}(\mathbf{x}, \mathbf{y}, \lambda, \mu) \subset \text{Hilb}^{dF,\bullet}(X)$$

parameterize subschemes whose maximal Cohen-Macaulay subscheme is

$$C = \bigcup_{i=1}^n (\lambda^{(i)} F_{x_i}) \bigcup_{j=1}^m (\mu^{(j)} F_{y_j}).$$

Since the only nodes of C_{red} are z_1, \dots, z_m (adopting the notation of Section 5) our fpqc cover is simpler in this case

$$\mathcal{U}_{\text{fib}} = \left\{ \widehat{X}_{z_1}, \dots, \widehat{X}_{z_m}, \widehat{X}_{F_{y_1}^{\circ}}, \dots, \widehat{X}_{F_{y_m}^{\circ}}, \widehat{X}_{F_{x_1}}, \dots, \widehat{X}_{F_{x_n}}, W \right\},$$

where our notation is the same as in Definition 10 except that

$$F_{y_j}^{\circ} = F_{y_j} - \{z_j\}, \quad W = X - C_{\text{red}}.$$

With virtually the same proof, we obtain the following analog of Lemma 11:

Lemma 17. *The following equation holds in $K_0(\text{Var}_{\mathbb{C}})((p))$*

$$\begin{aligned} \Sigma_{\text{fib}}^{\bullet}(\mathbf{x}, \mathbf{y}, \boldsymbol{\lambda}, \boldsymbol{\mu}) &= p^{\chi(\mathcal{O}_C)} \cdot \text{Hilb}^{\bullet}(W) \cdot \prod_{i=1}^n \text{Hilb}^{\bullet}(\widehat{X}_{F_i}, \lambda^{(i)} F_{x_i}) \\ &\quad \cdot \prod_{j=1}^m \text{Hilb}^{\bullet}(\widehat{X}_{F_{y_j}^{\circ}}, \mu^{(j)} F_{y_j}^{\circ}) \cdot \text{Hilb}^{\bullet}(\widehat{X}_{z_j}, \widehat{C}_{z_j}). \end{aligned}$$

We choose the same set of formal local coordinates at each point as we did in Section 5 and by the same reasoning as in that section, we find

$$\begin{aligned} e(\text{Hilb}^{\bullet}(\widehat{X}_{z_j}, \widehat{C}_{z_j})) &= \widetilde{V}_{\mu^{(j)} \mu^{(j)'} \emptyset}, \\ e(\text{Hilb}^{\bullet}(W)) &= \widetilde{V}_{\emptyset \emptyset \emptyset}^{e(W)}, \\ e(\text{Hilb}^{\bullet}(\widehat{X}_{F_{x_i}}, \lambda^{(i)} F_{x_i})) &= \widetilde{V}_{\lambda^{(i)} \emptyset \emptyset}^{e(F_{x_i})}, \\ e(\text{Hilb}^{\bullet}(\widehat{X}_{F_{y_j}^{\circ}}, \mu^{(j)} F_{y_j}^{\circ})) &= \widetilde{V}_{\mu^{(j)} \emptyset \emptyset}^{e(F_{y_j}^{\circ})}. \end{aligned}$$

Now since $\chi(\mathcal{O}_C) = 0$, $e(F_{x_i}) = e(F_{y_j}^{\circ}) = 0$, and

$$e(W) = e(S) - m,$$

we have that

$$\begin{aligned} f_d^{\text{fib}}(\mathbf{ax} + \mathbf{by}) &:= e\left((\rho_d^{\text{fib}})^{-1}(\mathbf{ax} + \mathbf{by})\right) \\ &= \sum_{\lambda \vdash \mathbf{a}} \sum_{\mu \vdash \mathbf{b}} e(\Sigma_{\text{fib}}^{\bullet}(\mathbf{x}, \mathbf{y}, \mathbf{a}, \mathbf{b})) \\ &= \sum_{\lambda \vdash \mathbf{a}} \sum_{\mu \vdash \mathbf{b}} \widetilde{V}_{\emptyset \emptyset \emptyset}^{e(S)} \prod_{j=1}^m \frac{\widetilde{V}_{\mu^{(j)} \mu^{(j)'} \emptyset}}{\widetilde{V}_{\emptyset \emptyset \emptyset}}. \end{aligned}$$

We may rewrite the above as

$$f_d^{\text{fib}}(\mathbf{ax} + \mathbf{by}) = \widetilde{V}_{\emptyset \emptyset \emptyset}^{e(S)} \prod_{i=1}^n g_{\text{fib}}(a_i) \prod_{j=1}^m h_{\text{fib}}(b_j),$$

where

$$g_{\text{fib}}(a) = \sum_{\lambda \vdash a} 1 \quad h_{\text{fib}}(b) = \sum_{\mu \vdash b} \frac{\widetilde{V}_{\mu \mu' \emptyset}}{\widetilde{V}_{\emptyset \emptyset \emptyset}}.$$

We then get the following result, analogous to Corollary 9, with a similar proof

$$\widehat{\text{DT}}_{\text{fib}}(X) = \widetilde{V}_{\emptyset \emptyset \emptyset}^{e(S)} \cdot \left(\sum_{\lambda} q^{|\lambda|} \right)^{e(B) - e(S)} \cdot \left(\sum_{\mu} \frac{\widetilde{V}_{\mu \mu' \emptyset}}{\widetilde{V}_{\emptyset \emptyset \emptyset}} q^{|\mu|} \right)^{e(S)}.$$

Substituting in the equations in Lemma 14, using the well known generating function for 2D-partitions, and applying [6, eqn (1)] we get

$$\widehat{\text{DT}}_{\text{fib}}(X) = M(p)^{e(S)} \cdot \left(\prod_{d=1}^{\infty} (1 - q^d)^{-1} \right)^{e(B) - e(S)} \cdot \left(\prod_{d=1}^{\infty} (1 - q^d)^{-1} M(p, q^d) \right)^{e(S)}$$

which is easily seen to be equivalent to the formula for $\widehat{\text{DT}}_{\text{fib}}(X)$ given in Theorem 1. \square

8. INCLUDING THE BEHREND FUNCTION

The aim of this section is to prove Theorem 3, which says that up to an overall sign, the partition functions $\widehat{\text{DT}}(X)$ and $\text{DT}(X)$ are equal after the simple change of variables $y = -p$. In order to do this we will need to assume a conjecture about the Behrend function which we formulate below for general Calabi-Yau threefolds and may be of independent interest.

Let Y be any quasi-projective Calabi-Yau threefold. Let $C \subset Y$ be a (not necessarily reduced) Cohen-Macaulay curve with proper support. Assume that the singularities of C_{red} are locally toric⁵. Recall that by Definition 4,

$$\text{Hilb}^n(Y, C) = \{Z \subset Y \text{ such that } C \subset Z \text{ and } I_C/I_Z \text{ has finite length } n\}.$$

Note that $\text{Hilb}^n(Y, C) \subset \text{Hilb}(Y)$ and let ν denote the Behrend function on $\text{Hilb}(Y)$. Our conjecture is the following:

Conjecture 18.

$$\int_{\text{Hilb}^n(Y, C)} \nu \, de = (-1)^n \nu([C]) \int_{\text{Hilb}^n(Y, C)} de,$$

where $\nu([C])$ is the value of the Behrend function at the point $[C] \in \text{Hilb}(Y)$.

Remark 19. Conceivably, the condition that C_{red} has locally toric singularities could be weakened, although we do not have any evidence for this case. Our conjecture is true for Y a (globally) toric Calabi-Yau, with torus T , and $C \subset Y$ any T -fixed Cohen-Macaulay curve. In this case both sides of our conjecture can be computed by restricting to the T -fixed points, which are isolated. The Behrend function at such a fixed point P is given by $\nu(P) = (-1)^{\dim T_P \text{Hilb}(Y)}$, [3, Thm. 3.4]. The calculation of $(-1)^{\dim T_P \text{Hilb}(Y)}$ is done in [13]; specifically, the LHS of the equation in [13, Thm 2] is easily seen to be $(-1)^{\dim T_P \text{Hilb}(Y)}$ while the RHS clearly obeys the formula in our conjecture.

⁵This means that formally locally C_{red} is either smooth, nodal, or the union of the three coordinate axes. That is at $p \in C_{\text{red}} \subset Y$ the ideal $\widehat{I}_{C_{\text{red}}} \subset \widehat{\mathcal{O}}_{Y,p}$ is given by (x_1, x_2) , $(x_1, x_2 x_3)$, or $(x_1 x_2, x_2 x_3, x_1 x_3)$ for some isomorphism $\widehat{\mathcal{O}}_{Y,p} \cong \mathbb{C}[[x_1, x_2, x_3]]$.

One could also make the much stronger conjecture that

$$\nu([Z]) = (-1)^n \nu([C]),$$

for all $[Z] \in \text{Hilb}^n(Y, C)$. This would of course imply our conjecture as stated. However, we do not know whether this stronger version holds, even in the case where Y is \mathbb{C}^3 and C is empty. In this case, this stronger conjecture says that the Behrend function on $\text{Hilb}^n(\mathbb{C}^3)$ is the constant function $(-1)^n$.

8.1. Proof of Theorem 3.

The Behrend function of any scheme is invariant under automorphisms. In particular, it is constant on the orbits of the \mathbb{C}^* action on $\text{Hilb}(X)$. We thus have

$$\text{DT}(X) = \int_{\text{Hilb}^{\bullet, \bullet}(X)} \nu \, de = \int_{\text{Hilb}^{\bullet, \bullet}(X)^{\mathbb{C}^*}} \nu \, de = \int_{\text{Hilb}_{\text{pCP}}^{\bullet, \bullet}(X)} \nu \, de$$

and so

$$\text{DT}(X) = \int_{\text{Sym}^{\bullet}(B)} (\rho_{\bullet})_*(\nu) \, de.$$

Let $f_d^\nu = (\rho_d)_*(\nu)$ so that in the notation of Section 4, we have

$$f_d^\nu(\mathbf{ax} + \mathbf{by}) = \int_{\rho_d^{-1}(\mathbf{ax} + \mathbf{by})} \nu \, de.$$

Recall that for the partition function $\text{DT}(X)$, the variable tracking the holomorphic Euler characteristic is y rather than p so $f_d^\nu(\mathbf{ax} + \mathbf{by}) \in \mathbb{Z}((y))$.

By equation (3) we have

$$f_d^\nu(\mathbf{ax} + \mathbf{by}) = \sum_{\lambda \vdash \mathbf{a}} \sum_{\mu \vdash \mathbf{b}} \int_{\Sigma^{\bullet}(\mathbf{x}, \mathbf{y}, \lambda, \mu)} \nu \, de.$$

Recall that $\Sigma^{\bullet}(\mathbf{x}, \mathbf{y}, \lambda, \mu)$ parameterizes subschemes $Z \subset X$ such that the maximal Cohen-Macaulay subscheme of Z is the partition thickened comb curve

$$C = B \cup_i (\lambda^{(i)} F_{x_i}) \cup_j (\mu^{(j)} F_{y_j}).$$

In other words, $\Sigma^{\bullet}(\mathbf{x}, \mathbf{y}, \lambda, \mu)$ is essentially equal to the local Hilbert scheme $\text{Hilb}^{\bullet}(X, C)$ (Definition 4) except that the latter is indexed by the length of I_C/I_Z whereas $\Sigma^{\bullet}(\mathbf{x}, \mathbf{y}, \lambda, \mu)$ is indexed by $\chi(\mathcal{O}_Z)$. Consequently

$$\Sigma^{\bullet}(\mathbf{x}, \mathbf{y}, \lambda, \mu) = y^{\chi(\mathcal{O}_C)} \text{Hilb}^{\bullet}(X, C)$$

and so

$$f_d^\nu(\mathbf{ax} + \mathbf{by}) = \sum_{\lambda \vdash \mathbf{a}} \sum_{\mu \vdash \mathbf{b}} y^{\chi(\mathcal{O}_C)} \sum_{n=0}^{\infty} y^n \int_{\text{Hilb}^n(X, C)} \nu \, de.$$

We apply Conjecture 18 to the above and also use $\nu([C]) = (-1)^{\chi(\mathcal{O}_S) - \chi(\mathcal{O}_C)}$, the highly non-trivial result given in Corollary 23 and proved in the next section.

$$\begin{aligned} f_d^\nu(\mathbf{ax} + \mathbf{by}) &= \sum_{\lambda \vdash \mathbf{a}} \sum_{\mu \vdash \mathbf{b}} y^{\chi(\mathcal{O}_C)} \sum_{n=0}^{\infty} y^n (-1)^n \nu([C]) \int_{\text{Hilb}^n(X, C)} de \\ &= (-1)^{\chi(\mathcal{O}_S)} \sum_{\lambda \vdash \mathbf{a}} \sum_{\mu \vdash \mathbf{b}} \sum_{n=0}^{\infty} (-y)^{\chi(\mathcal{O}_C) + n} \int_{\text{Hilb}^n(X, C)} de. \end{aligned}$$

After the substitution $-y = p$, we find that the above is equivalent to

$$f_d^\nu(\mathbf{ax} + \mathbf{by}) = (-1)^{\chi(\mathcal{O}_S)} f_d(\mathbf{ax} + \mathbf{by}).$$

It follows that

$$\text{DT}(X) = (-1)^{\chi(\mathcal{O}_S)} \widehat{\text{DT}}(X)$$

after the substitution $p = -y$ as asserted by Theorem 3.

The case of $\text{DT}_{\text{fib}}(X)$ (previously shown by Toda) proceeds similarly except that it does not require the difficult deformation result of the next section. Indeed, in this case, we only need to know that the value of the Behrend function at a partition thickened fiber curve is 1

$$\nu\left(\left[\bigcup_i (\lambda^{(i)} F_{x_i})\right]\right) = 1.$$

This follows from the fact that subschemes in X of the form $p^{-1}(Z)$, where Z is a zero dimensional subscheme of T , form a component of $\text{Hilb}(X)$ which is isomorphic to the Hilbert scheme of points on T and hence smooth and even dimensional. While this can be proven directly, one can also do a similar (but easier) computation as we do in the proof of Theorem 21 in Section 9.

9. SMOOTHNESS AND INFINITESIMAL DEFORMATIONS

In this section we show that the locus of partition thickened comb curves lies in the non-singular locus of $\text{Hilb}(X)$ and we compute the dimension of $\text{Hilb}(X)$ at those points. As a corollary, we determine the value of the Behrend function at the points of the Hilbert scheme corresponding to partition thickened comb curves. This is the key technical result required in Section 8 to promote our computation of $\widehat{\text{DT}}(X)$ to a computation of the Behrend function version $\text{DT}(X)$.

We begin by stating the three main results of this section.

Theorem 20. *Let $B \subset T$ be a smooth curve contained in a smooth surface T . Define $V_l \subset \text{Hilb}^d(T)$ to be the locus of points parameterizing zero dimensional subschemes $Z \subset T$ of length n such that the length of the*

scheme theoretic intersection $Z \cap B$ is l . Then V_l is locally closed and smooth of dimension $2d - l$.

Theorem 21. *Let $\lambda^{(1)}, \dots, \lambda^{(n)}$ be partitions and let $C = B \cup_i (\lambda^{(i)} F_{x_i})$ be a partition thickened comb curve. The Zariski tangent space of $\text{Hilb}(X)$ at the point $[C]$, which is given by $\text{Hom}(I_C, \mathcal{O}_C) \cong \text{Ext}_0^1(I_C, I_C)$, has dimension*

$$h^0(N_{B/T}) + \sum_{i=1}^n \left(2|\lambda^{(i)}| - \lambda_1^{(i)} \right).$$

Theorem 22. *The locus of partition thickened comb curves is contained in the non-singular locus of $\text{Hilb}(X)$.*

Corollary 23. *The value of the Behrend function at $[C] \in \text{Hilb}(X)$ for a partition thickened comb curve $C = B \cup_i (\lambda^{(i)} F_{x_i})$ is given by*

$$\nu([C]) = (-1)^{\chi(\mathcal{O}_S) - \chi(\mathcal{O}_C)}.$$

Proof. By [2], the Behrend function on a smooth scheme V is $(-1)^{\dim V}$ and so by Theorems 22 and 21

$$\nu([C]) = (-1)^{h^0(N_{B/X})} \prod_{i=1}^n (-1)^{\lambda_1^{(i)}}.$$

Lemma 27 and Lemma 12 say that

$$h^0(N_{B/X}) = \chi(\mathcal{O}_S) - \chi(\mathcal{O}_B), \quad \chi(\mathcal{O}_C) = \chi(\mathcal{O}_B) - \sum_i \lambda_1^{(i)}$$

which, when substituted into the above, prove the corollary. \square

The most difficult of the above results is Theorem 21 and its proof occupies the majority of this section.

Our method for computing the dimension of deformation spaces is an adaption of Haiman's method for computing infinitesimal deformations of zero dimensional subschemes on a surface [9]. Indeed, the proof of Theorem 20 follows directly using Haiman's argument. For Theorem 21, we use Haiman's method to study local deformations of C in the formal neighborhoods of the points x_i , but we use the global geometry to keep track of which local deformations extend.

9.1. Setup for the proof of Theorem 21.

For notational simplicity we first treat the case where there is a single partition thickened fiber $F = F_x$ at $x \in B$, that is

$$C = B \cup \lambda F,$$

where $(\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_l)$ is an integer partition of length l .

Consider the divisors

$$S, \quad R = \text{Tot}(K_S|_F), \quad T = \text{Tot}(K_S|_B)$$

and let (r, s, t) be formal local coordinates at x such that

$$R = \{r = 0\}, \quad S = \{s = 0\}, \quad T = \{t = 0\}.$$

The formal local ring $\widehat{\mathcal{O}}_{X,x} \cong \mathbb{C}[[r, s, t]]$ has a basis as a \mathbb{C} -vector space given by monomials $\{r^\rho s^\sigma t^\tau\}$ for $(\rho, \sigma, \tau) \in (\mathbb{Z}_{\geq 0})^3$. We visualize these basis vectors as unit cubes in the positive octant of \mathbb{R}^3 with the monomial $r^\rho s^\sigma t^\tau$ corresponding to the cube whose corner closest to the origin is at (ρ, σ, τ) .

9.2. Exact sequences.

The ideal sheaf I_C has a locally free resolution of the form

$$(7) \quad 0 \rightarrow \oplus_\beta R_\beta \rightarrow \oplus_\alpha G_\alpha \rightarrow I_C \rightarrow 0,$$

where G_α (the “generators”) and R_β (the “relations”) are of the form

$$\mathcal{O}(-\rho R - \sigma S - \tau T).$$

Indeed, we can explicitly take the collection of (ρ, σ, τ) for G_α to be

$$\{(\lambda_1, 0, 1), (\lambda_2, 1, 0), (\lambda_3, 2, 0), \dots, (\lambda_l, l-1, 0), (0, l, 0)\}.$$

Note that the τ component is 1 for the first generator, and zero for all others.

We also have the sequence

$$0 \rightarrow \mathcal{O}_C \rightarrow \mathcal{O}_B \oplus \mathcal{O}_{\lambda F} \rightarrow \mathcal{O}_{\lambda_1 x} \rightarrow 0,$$

where $\lambda_1 x = B \cap \lambda F$ is the length λ_1 subscheme of B supported at x .

By standard homological algebra, we have that $\text{Hom}(I_C, \mathcal{O}_C)$ is H^0 of the complex

$$\text{Hom}([\oplus_\beta R_\beta \rightarrow \oplus_\alpha G_\alpha], [\mathcal{O}_B \oplus \mathcal{O}_{\lambda F} \rightarrow \mathcal{O}_{\lambda_1 x}]).$$

Namely, we have that $\text{Hom}(I_C, \mathcal{O}_C)$ is given by the kernel of the map

$$\text{Hom}(\oplus_\alpha G_\alpha, \mathcal{O}_B \oplus \mathcal{O}_{\lambda F}) \xrightarrow{\Phi_1 \oplus \Phi_2} \text{Hom}(\oplus_\alpha G_\alpha, \mathcal{O}_{\lambda_1 x}) \oplus \text{Hom}(\oplus_\beta R_\beta, \mathcal{O}_B \oplus \mathcal{O}_{\lambda F}).$$

This identification of $\text{Hom}(I_C, \mathcal{O}_C)$ has a straightforward interpretation: a homomorphism $I_C \rightarrow \mathcal{O}_C$ is determined by what it is on each of the generators of I_C , considered as maps to \mathcal{O}_B and to $\mathcal{O}_{\lambda F}$. To be in the kernel of Φ_1 just means that these maps should agree on $B \cap \lambda F$ and to be in the kernel of Φ_2 means that the images must obey the module relations. We will make this combinatorially more explicit by studying the restriction of the homomorphisms $\oplus_\alpha G_\alpha \rightarrow \mathcal{O}_B \oplus \mathcal{O}_{\lambda F}$ to $\widehat{X}_x \cong \text{Spec } \mathbb{C}[[r, s, t]]$.

FIGURE 2. Monomials in the local ring $\widehat{\mathcal{O}}_{X,x} \cong \mathbb{C}[[r, s, t]]$ are represented by cubes. Cubes shown are the monomials in $\widehat{\mathcal{O}}_{C,x}$. The grey balls are located at monomials which generate $\widehat{I}_{C,x}$

9.3. Combinatorics of Haiman arrows.

When restricted to the local ring $\widehat{\mathcal{O}}_{X,x} \cong \mathbb{C}[[r, s, t]]$, \mathcal{O}_C is spanned over \mathbb{C} by the monomials $r^\rho s^\sigma t^\tau$, where (ρ, σ, τ) are of the form $(\rho, 0, 0)$ or $(\rho, \sigma, \tau)_{(\rho, \sigma) \in \lambda}$ and I_C is spanned by the complementary monomials. As previously discussed, we view these monomials as cubes in the positive octant, see Figure 2.

We call the cubes corresponding to $(\rho, 0, 0)$ and $(\rho, \sigma, \tau)_{(\rho, \sigma) \in \lambda}$ the B -cubes and λF -cubes respectively and the cubes in the union are called C -cubes. The complement of the C -cubes are the I_C -cubes.

A Haiman arrow

$$(\rho, \sigma, \tau) \rightarrow (\rho', \sigma', \tau')$$

is a vector whose tail (ρ, σ, τ) is an I_C -cube and whose head (ρ', σ', τ') is a C -cube.

The Haiman arrows form a basis for the \mathbb{C} -linear maps from $\widehat{I}_{C,x}$ to $\widehat{\mathcal{O}}_{C,x}$. We wish to determine a basis for $\text{Hom}(I_C, \mathcal{O}_C)$ in terms of Haiman arrows.

The generators of I_C correspond to the cubes in the corners of the set of I_C -cubes. They are located at (ρ, σ, τ) where (ρ, σ) are the corners just outside of λ and $\tau = 0$ unless $\sigma = 0$ in which case $\tau = 1$ (they are indicated by the grey balls in Figure 2). A generator at (ρ, σ, τ) corresponds to the

image of $G_\alpha \rightarrow \mathcal{O}$ where $G_\alpha \cong \mathcal{O}(-\rho R - \sigma S - \tau T)$. The summands of

$$\mathrm{Hom}(\oplus_\alpha G_\alpha, \mathcal{O}_B \oplus \mathcal{O}_{\lambda F}) \cong \oplus_\alpha H^0(B, G_\alpha^\vee \otimes \mathcal{O}_B) \oplus H^0(F, G_\alpha^\vee \otimes \mathcal{O}_{\lambda F})$$

are interpreted as follows. For $G_\alpha \cong \mathcal{O}(-\rho R - \sigma S - \tau T)$, a homomorphism in $\mathrm{Hom}(G_\alpha, \mathcal{O}_B)$ or $\mathrm{Hom}(G_\alpha, \mathcal{O}_{\lambda F})$ is determined by a linear combination of Haiman arrows from (ρ, σ, τ) to (respectively) some B -cube or λF -cube (ρ', σ', τ') . The location of the head of such a Haiman arrow is determined by the order of vanishing of the corresponding section of $H^0(B, G_\alpha^\vee \otimes \mathcal{O}_B)$ or $H^0(F, G_\alpha^\vee \otimes \mathcal{O}_{\lambda F})$ — the head will occur at (ρ', σ', τ') if the corresponding section is order $r^{\rho'} s^{\sigma'} t^{\tau'}$.

We wish to determine a basis for $\mathrm{Hom}(I_C, \mathcal{O}_C) \cong \mathrm{Ker}(\Phi_1 \oplus \Phi_2)$ in terms of Haiman arrows. To be in the kernel of Φ_1 just means that a Haiman arrow whose head is both a B -cube and a λF -cube must arise as sections of both $H^0(B, G_\alpha^\vee \otimes \mathcal{O}_B)$ and $H^0(F, G_\alpha^\vee \otimes \mathcal{O}_{\lambda F})$. As for the kernel of Φ_2 , the key observation is the following, essentially due to Haiman [9]:

Remark 24. The equations defining the kernel of Φ_2 equate two Haiman arrows which are obtained from one another by translation through other Haiman arrows. Moreover, if a Haiman arrow can be translated so that its head passes into an octant with a negative coordinate (without its tail ever leaving the I_C -cubes) then it must be zero.

We now analyze the possible equivalence classes of Haiman arrows.

9.4. Haiman arrows to λF -cubes.

Let $G_\alpha \cong \mathcal{O}(-\rho R - \sigma S - \tau T)$ be a generating line bundle and consider the sections $H^0(F, G_\alpha^\vee \otimes \mathcal{O}_{\lambda F})$. A basis for this vector space corresponds to the possible Haiman arrows $(\rho, \sigma, \tau) \rightarrow (\rho', \sigma', \tau')$ to λF -cubes. Since the normal bundle of F in X is trivial, $\mathcal{O}(R)$ and $\mathcal{O}(S)$ are trivial restricted to F . Thus

$$G_\alpha^\vee \otimes \mathcal{O}_{\lambda F} \cong \mathcal{O}_{\lambda F}(\rho R + \sigma S + \tau T) \cong \mathcal{O}_{\lambda F}(\tau x).$$

Since τ is either 0 or 1 for the generators G_α , the Haiman arrows correspond to

$$H^0(F, \mathcal{O}_{\lambda F}) \text{ if } \tau = 0, \quad H^0(F, \mathcal{O}_{\lambda F}(x)) \text{ if } \tau = 1.$$

In both cases, this space has a basis of sections which in the local coordinates are given by $\{r^{\rho'} s^{\sigma'} t^{\tau'}\}_{(\rho', \sigma') \in \lambda}$. Note that the sections we consider above are uniquely determined by their value on the formal neighborhood $\widehat{X}_x \cong \mathrm{Spec} \mathbb{C}[[r, s, t]]$, a property which uses crucially the fact that the genus of F is 1.

We have seen that the possible Haiman arrows to λF -cubes are given by

$$(\rho, \sigma, \tau) \rightarrow (\rho', \sigma', \tau'),$$

FIGURE 3. Examples of Haiman arrows to λF -cubes. The green arrows are non-zero and the red arrows are necessarily zero.

where (ρ, σ, τ) is a generating cube, $\tau' = \tau$ and $(\rho', \sigma') \in \lambda$. In particular, the direction of the arrows is horizontal since there is no τ component in $(\rho - \rho', \sigma - \sigma', 0)$.

Since all the Haiman arrows to λF -cubes are horizontal, we view them from above in the (r, s) plane (see Figure 3).

If the direction of the Haiman arrow is strictly southwest (i.e. it has strictly negative ρ and σ components), then by translating (see Remark 24) along the contour of λ to the edge of the s -axis, the arrow can be equated to an arrow whose head has a negative ρ component and is thus zero. There are no strictly northeast pointing Haiman arrows, so all non-zero Haiman arrows must be weakly northwest pointing or weakly southeast pointing. Translating a weakly northwest pointing arrow as far to the northwest as possible, we find that its head will either cross the s -axis (and hence be 0) or it will be at the top of a column of λ and its tail just outside a row. Indeed, for each square in λ , there is exactly one equivalence class of weakly northwest pointing Haiman arrows represented by the arrow going from just outside the box's row to the top of the box's column. Similarly, there is one equivalence class of weakly southeast pointing Haiman arrows for each box in λ represented by the arrow going from just outside the top of the box's column to the end of the box's row.

The above accounts for precisely $2|\lambda|$ different equivalence classes of Haiman arrows to λF -cubes. However, λ_1 of these arrows have their head in a B -cube, namely the southeast pointing arrows whose tails are just above the top of λ and whose head is the last square in the first row of λ . Note that the northwest pointing Haiman arrows whose heads are in the first row of λ are necessarily strictly west pointing and hence originate at the generator whose τ component is 1. Therefore the head of these arrows also have τ component 1 and so they are not B -cubes.

We thus have exactly $2|\lambda| - \lambda_1$ distinct equivalence classes of Haiman arrows to λF -cubes which are not also arrows to B -cubes.

9.5. Haiman arrows to B -cubes.

Any non-zero Haiman arrow to a B -cube must have a tail with coordinates $(\rho, 0, 1)$ or $(\rho, 1, 0)$ since if not, it could be translated (see Remark 24) to an arrow whose head has negative τ or σ coordinates by first translating sufficiently far in the positive ρ -direction and then translating the tail so that it is just outside of the B -cubes. A Haiman arrow to a B -cube whose tail is $(\rho, 0, 1)$ or $(\rho, 1, 0)$ corresponds respectively to a section in $H^0(B, \mathcal{O}_B(\rho R + T))$ or $H^0(B, \mathcal{O}_B(\rho R + S))$. Since

$$\mathcal{O}_B(R) \cong \mathcal{O}_B(x), \quad \mathcal{O}_B(T) \cong N_{B/S}, \quad \mathcal{O}_B(S) \cong N_{B/T},$$

we see that the Haiman arrows from $(\rho, 0, 1)$ or $(\rho, 1, 0)$ to B -cubes are given by

$$H^0(B, N_{B/S}(\rho x)) \quad \text{or} \quad H^0(B, N_{B/T}(\rho x))$$

respectively. The head of such a Haiman arrow is $(\rho', 0, 0)$ where ρ' is the order of vanishing at x of the corresponding section.

Lemma 25. *Let $(\rho, 0, 1) \rightarrow (\rho', 0, 0)$ or $(\rho, 1, 0) \rightarrow (\rho', 0, 0)$ be a non-zero Haiman arrow. Then $\rho' \geq \rho$.*

Proof. Consider a Haiman arrow $(\rho, 0, 1) \rightarrow (\rho', 0, 0)$ with $\rho' < \rho$. Then this arrow can be translated so that its head is a λF -cube, however we saw in the previous subsection that Haiman arrows to λF -cubes must be horizontal and so this must be zero. Consider next a Haiman arrow $(\rho, 1, 0) \rightarrow (\rho', 0, 0)$ with $\rho' < \rho$. Then this arrow maybe translated so that it is a strictly southwest pointing Haiman arrow to an λF -cube which we showed in the previous subsection must be zero⁶. \square

By the lemma, we conclude that the only sections of $H^0(B, N_{B/S}(\rho x))$ or $H^0(B, N_{B/T}(\rho x))$ which correspond to non-zero Haiman arrows vanish to order at least ρ at x , and thus they are necessarily in the image of the maps

$$\begin{aligned} H^0(B, N_{B/S}) &\rightarrow H^0(B, N_{B/S}(\rho x)), \\ H^0(B, N_{B/T}) &\rightarrow H^0(B, N_{B/T}(\rho x)). \end{aligned}$$

By Lemma 27, $H^0(B, N_{B/S}) = 0$. On the other hand, $H^0(B, N_{B/T})$ can be non-zero and these deformations do occur, they correspond to global deformations of B in the K_S -direction.

⁶Are you still with us dear reader? We are deep in the weeds now, but are almost done.

In conclusion, we have completely classified all possible Haiman arrows up to equivalence and have thus constructed an explicit basis for

$$\mathrm{Hom}(I_C, \mathcal{O}_C) \cong \mathrm{Ker}(\Phi_1 \oplus \Phi_2).$$

They consist of the $2|\lambda| - \lambda_1$ Haiman arrows to λF -cubes which do not go to B -cubes and the $h^0(B, N_{B/T}) = h^0(B, N_{B/X})$ dimensional space of Haiman arrows going to B -cubes. We have thus proved that

$$\dim \mathrm{Hom}(I_C, \mathcal{O}_C) = h^0(B, N_{B/T}) + 2|\lambda| - \lambda_1$$

for $C = B \cup \lambda F$. Our argument extends essentially word for word to the case where $C = B \cup_i (\lambda^{(i)} F_{x_i})$ has several partition thickened fibers. Whether the fiber is smooth or nodal plays no role. We have thus proved Theorem 21. \square

9.6. Proof of Theorem 22.

Let $C = B \cup_{i=1}^n (\lambda^{(i)} F_{x_i})$ be a partition thickened comb curve and let

$$d = \sum_{i=1}^n |\lambda^{(i)}|, \quad l = \sum_{i=1}^n \lambda_1^{(i)}.$$

To prove Theorem 22 it will suffice to construct a flat family of distinct subschemes of X , containing C as a member, and over a base W which is smooth and of dimension

$$h^0(N_{B/T}) + 2d - l.$$

Indeed, Theorem 21 then implies that the induced injective map $W \rightarrow \mathrm{Hilb}(X)$ is a local isomorphism and the assertion of Theorem 22 follows.

Let

$$H^0 := H^0(B, N_{B/T}),$$

and let

$$V_l \subset \mathrm{Hilb}^d(T)$$

be the stratum defined in Theorem 20. Let $W = H^0 \times V_l$ so by Theorem 20, W is smooth and of dimension $h^0(N_{B/T}) + 2d - l$. We wish to construct a family over W of distinct subschemes.

Since $T = \mathrm{Tot}(N_{B/T})$, given $\theta \in H^0$, we get an automorphism of T , which we call Θ , given by

$$\Theta : (p, v) \mapsto (p, v + \theta(p)),$$

where $p \in B$ and $v \in T|_p$.

We will construct a family of subschemes of X , flat over the base $H^0 \times V_l$, which over a point $(\theta, Z) \in H^0 \times V_l$ is the subscheme

$$C_\theta = \Theta(B) \cup p^{-1}(\Theta(Z)).$$

Clearly, all such subschemes are distinct, and moreover, every partition thickened comb curve is of the above form (with $\theta = 0$ so that $\Theta = \text{id}$).

Formally, we construct the universal subscheme

$$\mathcal{C} \subset H^0 \times V_l \times X$$

flat over $H^0 \times V_l$ as follows. Consider the diagram

$$\begin{array}{ccccc} & & H^0 \times V_l \times X & & \\ & & \uparrow i \quad \downarrow p & & \\ & & H^0 \times V_l \times T & \xrightarrow{\Theta} & H^0 \times V_l \times T \\ & & \downarrow \pi_1 & & \downarrow \pi_2 \\ \mathcal{B} & \hookrightarrow & H^0 \times T & & V_l \times T \longleftarrow \mathcal{Z}. \end{array}$$

In the above diagram, $\mathcal{Z} \subset V_l \times T$ is the family of subschemes of T induced by the universal subscheme over $\text{Hilb}^d(T)$, $\mathcal{B} \subset H^0 \times T$ is the family of curves in T given by H^0 , explicitly \mathcal{B} is given by the set of points $(\theta, p, \theta(p))$. The maps π_1 and π_2 are the obvious projections and the maps p and i are the projection and the zero section of the elliptic fibration $X \rightarrow T$. We are also adopting the general abuse of notation that we drop factors of the identity map from the notation, that is if $f : A \rightarrow B$ we denote also by f the map $f \times \text{id}_C : A \times C \rightarrow B \times C$.

Then the subscheme

$$\mathcal{C} = i(\pi_1^{-1}(\mathcal{B})) \cup (p \circ \Theta \circ \pi_2)^{-1}(\mathcal{Z}) \subset H^0 \times V_l \times X$$

is the desired universal subscheme over $H^0 \times V_l$. \square

9.7. Proof of Theorem 20.

The constructible function $\text{Hilb}^d(T) \rightarrow \mathbb{Z}$ given by

$$Z \mapsto \text{length}(Z \cap B)$$

is upper semi-continuous and thus V_l is locally closed.

There is a dense open set on V_l isomorphic to

$$\text{Sym}^l(B) \times \text{Hilb}^{d-l}(T - B),$$

which is clearly smooth and of dimension $2d - l$. Therefore, to prove the theorem it suffices to show that

$$\dim T_{[Z]}V_l = 2d - l,$$

where $Z \subset T$ is a subscheme which is set theoretically (but not necessarily scheme theoretically) supported on B . Moreover, we can easily reduce to the case where Z is supported at a single point $p \in B$. By choosing formal

local coordinates (r, s) on T at p such that $B = \{s = 0\}$, we are reduced to considering the case

$$T = \operatorname{Spec} \mathbb{C}[r, s], \quad B = \{s = 0\}, \quad \text{and } Z \subset T \text{ supported at } 0.$$

Finally, since $(\mathbb{C}^*)^2$ acts on V_l in this case, it suffices to compute $\dim T_{[Z]} V_l$ at $(\mathbb{C}^*)^2$ -fixed subschemes $Z \subset T$. Recall that the fixed subschemes are given by Z_λ (see Section 3) defined by monomial ideals $I_\lambda \subset \mathbb{C}[r, s]$ corresponding to partitions λ of d which in this case have $\lambda_1 = l$, because $\operatorname{leng}(Z_\lambda \cap B) = l$.

Therefore, we need only prove the following lemma:

Lemma 26. *Let $\lambda = (\lambda_1 \geq \dots \geq \lambda_k)$ be a partition of d with $\lambda_1 = l$. Let $Z_\lambda \subset \mathbb{C}^2 = \operatorname{Spec} \mathbb{C}[r, s]$ be defined by the monomial ideal*

$$I_\lambda = (r^{\lambda_1}, r^{\lambda_2} s, \dots, r^{\lambda_k} s^{k-1}, s^k).$$

Let $V_l \subset \operatorname{Hilb}^d(\mathbb{C}^2)$ be as in Theorem 20. Then

$$\dim T_{[Z_\lambda]} V_l = 2d - l.$$

Proof. The tangent space

$$T_{[Z_\lambda]} V_l \subset T_{[Z_\lambda]} \operatorname{Hilb}^d(\mathbb{C}^2)$$

is cut out by the equations obtained by linearizing the condition

$$\operatorname{leng}(Z \cap \{s = 0\}) = l$$

at Z_λ . In [9], M. Haiman has given a very explicit basis for $T_{Z_\lambda} \operatorname{Hilb}^d(\mathbb{C}^2)$ in terms of what we called Haiman arrows in Section 9.3. Namely, consider all Haiman arrows $(\rho, \sigma) \rightarrow (\rho', \sigma')$ of one of the following two forms:

- (1) $(\rho, \sigma) \rightarrow (\rho', \sigma')$ is a southeast pointing arrow with (ρ, σ) located at a box just above the top of a column of λ and (ρ', σ') located at a box which is the furthest to the right in a row of λ .
- (2) $(\rho, \sigma) \rightarrow (\rho', \sigma')$ is a northwest pointing arrow with (ρ, σ) located at a box just to the right of a row of λ and (ρ', σ') located at a box which is at the top of a column of λ .

There are $2d$ such arrows, d of each kind. The infinitesimal deformation corresponding to an arrow $(\rho, \sigma) \rightarrow (\rho', \sigma')$ is given by deforming the element $r^\rho s^\sigma \in I_\lambda$ to

$$r^\rho s^\sigma + \epsilon r^{\rho'} s^{\sigma'},$$

where $\epsilon^2 = 0$.

For each $\phi : (\rho, \sigma) \rightarrow (\rho', \sigma')$ let $I_{Z_\lambda}(\phi)$ be the corresponding deformed ideal and consider

$$\dim \left(\frac{\mathbb{C}[r, s]}{I_{Z_\lambda} + (s)} \right).$$

If $\sigma' > 0$ then $I_{Z_\lambda}(\phi) + (s) = I_{Z_\lambda} + (s)$: Haiman arrows $(\rho, \sigma) \rightarrow (\rho', \sigma')$ with $\sigma' > 0$ preserve the condition $\text{len}(Z \cap \{s = 0\}) = l$ and hence lie in $T_{[Z_\lambda]}V_l$.

If $\sigma' = 0$ there are two possibilities:

- (1) (ρ, σ) is just above a column of λ and $(\rho', \sigma') = (\lambda_1 - 1, 0)$, or
- (2) ϕ is of the form $(\lambda_1, 0) \rightarrow (\rho', 0)$ for $0 \leq \rho' < \lambda_1$.

In Case 2, we have

$$\frac{\mathbb{C}[r, s]}{I_{Z_\lambda}(\phi) + (s)} \cong \frac{\mathbb{C}[r]}{(r^{\lambda_1} + \epsilon r^{\rho'})},$$

which has dimension $\lambda_1 = l$ for all values of ϵ since $r^{\lambda_1} + \epsilon r^{\rho'}$ has degree λ_1 for all values of ϵ .

In Case 1, we have

$$\frac{\mathbb{C}[r, s]}{I_{Z_\lambda}(\phi) + (s)} \cong \frac{\mathbb{C}[r]}{(r^{\lambda_1}, \epsilon r^{\lambda_1-1})}$$

which, for non-zero values of ϵ , has dimension $\lambda_1 - 1$.

Thus we have found that $T_{[Z_\lambda]}V_l$ is spanned by all the arrows in the Haiman basis except for the $\lambda_1 = l$ arrows given by Case 1 above and therefore $\dim T_{[Z_\lambda]}V_l = 2d - l$. \square

APPENDIX A. ODDS AND ENDS

A.1. Elliptic surfaces.

Let $p : S \rightarrow B$ be a non-trivial elliptic surface with section $B \subset S$. For simplicity, we assume that all singular fibers are irreducible nodal rational curves.

Let $X = \text{Tot}(K_S)$ and let $T = \text{Tot}(K_S|_B)$, then clearly we have

$$N_{B/X} \cong N_{B/S} \oplus N_{B/T}.$$

Lemma 27. $h^0(N_{B/S}) = 0$ and $h^0(N_{B/T}) = \chi(\mathcal{O}_S) - \chi(\mathcal{O}_B)$.

Proof. By a well known fact about elliptic surfaces (see [8] or [15, III.1.1]),

$$K_S \cong p^*(K_B \otimes L),$$

where

$$L^\vee = R^1 p_* \mathcal{O}_S.$$

Consequently, $c_1(K_S)^2 = 0$ and so Hirzebruch-Riemann-Roch says

$$\chi(\mathcal{O}_S) = \frac{e(S)}{12} > 0,$$

where positivity of $e(S)$ follows by pushing forward the Euler characteristic measure on S to B

$$e(S) = \int_S de = \int_B p_*(1) de = \# \text{ of singular fibers.}$$

On the other hand

$$\begin{aligned} \chi(\mathcal{O}_S) &= \chi(R^\bullet p_* \mathcal{O}_S) \\ &= \chi(\mathcal{O}_B) - \chi(L^\vee) \\ &= \deg(L). \end{aligned}$$

By adjunction

$$N_{B/S} \cong (K_S^\vee|_B) \otimes K_B \cong L^\vee.$$

Thus $\deg(N_{B/S}) = \deg(L^\vee) = -\chi(\mathcal{O}_S) < 0$ and so $h^0(N_{B/S}) = 0$.

Since

$$N_{B/T} = K_S|_B = K_B \otimes L,$$

we see that

$$h^1(N_{B/T}) = h^1(K_B \otimes L) = h^0(L^\vee) = h^0(N_{B/S}) = 0,$$

and therefore

$$\begin{aligned} h^0(N_{B/T}) &= \chi(N_{B/T}) \\ &= \deg(K_B) + \deg(L) + 1 - g(B) \\ &= \chi(\mathcal{O}_S) + g(B) - 1 \\ &= \chi(\mathcal{O}_S) - \chi(\mathcal{O}_B). \end{aligned} \quad \square$$

By our assumption that S is not a product,

$$p^* : \text{Pic}^0(B) \xrightarrow{\cong} \text{Pic}^0(S)$$

is an isomorphism [15, VII.1.1]. For any $\beta \in H_2(S)$, we denote by $\text{Hilb}^\beta(S)$ the Hilbert scheme of effective divisors on S in class β .

Denote by $B \in H_2(S)$ the class of the section $B \subset S$ and by $F \in H_2(S)$ the class of the fiber. Then we have the following commutative diagram

$$\begin{array}{ccc} \text{Sym}^d(B) & \longrightarrow & \text{Pic}^d(B) \\ \downarrow p^* & & \cong \downarrow p^* \\ \text{Hilb}^{dF}(S) & \longrightarrow & \text{Pic}^{dF}(S) \\ \downarrow +B & & \cong \downarrow \otimes \mathcal{O}_S(B) \\ \text{Hilb}^{B+dF}(S) & \longrightarrow & \text{Pic}^{B+dF}(S). \end{array}$$

The horizontal arrows are Abel-Jacobi maps. The vertical arrows are induced by pull-back and adding the section $B \subset S$.

Lemma 28. *The above maps induce a bijective morphism*

$$\mathrm{Sym}^d(B) \rightarrow \mathrm{Hilb}^{B+dF}(S).$$

Proof. Clearly p^* gives an isomorphism $\mathrm{Sym}^d(B) \cong \mathrm{Hilb}^{dF}(S)$ and $+B$ defines a closed embedding $\mathrm{Hilb}^{dF}(S) \hookrightarrow \mathrm{Hilb}^{B+dF}(S)$. Thus it suffices to show

$$\mathrm{Sym}^d(B) \rightarrow \mathrm{Hilb}^{B+dF}(S)$$

is surjective on closed points.

For surjectivity, suppose D' is an effective divisor with class $B + dF$ which does *not* lie in the image. Firstly, we note that for any fiber F we have $D' \cdot F = 1$. Therefore D' contains a section $B' \subset S$ as an effective summand. Moreover $B \neq B'$ or else D' would lie in the image. Next, we take any D in the image and compare D and D' . Then

$$\mathcal{O}_S(D - D') \in \mathrm{Pic}^0(S) \cong \mathrm{Pic}^0(B).$$

Therefore after re-arranging we find that there are distinct fibers F_{x_i}, F_{y_j} and $a_i \geq 0, b_j \geq 0$ such that

$$B + \sum_i a_i F_{x_i} \sim_{\mathrm{lin}} B' + \sum_j b_j F_{y_j},$$

where \sim_{lin} denotes linear equivalence. Hence there exists a pencil $\{C_t\}_{t \in \mathbb{P}^1}$ of effective divisors such that

$$C_0 = B + \sum_i a_i F_{x_i}, \quad C_\infty = B' + \sum_j b_j F_{y_j}.$$

Now fix a smooth fiber F . Then $C_t \cdot F = 1$ for any $t \in \mathbb{P}^1$, so we get a morphism

$$\mathbb{P}^1 \longrightarrow F, \quad t \mapsto C_t \cap F.$$

But F is a smooth elliptic curve so this map is constant. We conclude

$$B \cap F = C_0 \cap F = C_\infty \cap F = B' \cap F.$$

Since F was chosen arbitrary, we deduce that $B = B'$ which is a contradiction. \square

A.2. Weighted Euler characteristics of symmetric products.

In this section we prove the following formula for the weighted Euler characteristic of symmetric products.

Lemma 29. *Let B be a scheme of finite type over \mathbb{C} and let $e(B)$ be its topological Euler characteristic. Let $g : \mathbb{Z}_{\geq 0} \rightarrow \mathbb{Z}((p))$ be any function with $g(0) = 1$. Let $G : \text{Sym}^d(B) \rightarrow \mathbb{Z}((p))$ be the constructible function defined by*

$$G(\mathbf{ax}) = \prod_i g(a_i),$$

for all $\mathbf{ax} = \sum_i a_i x_i \in \text{Sym}^d(B)$ where $x_i \in B$ are distinct closed points. Then

$$\sum_{d=0}^{\infty} q^d \int_{\text{Sym}^d(B)} G \, de = \left(\sum_{a=0}^{\infty} g(a) q^a \right)^{e(B)}.$$

Remark 30. In the special case where $g = G \equiv 1$, the lemma recovers MacDonald's formula

$$\sum_{d=0}^{\infty} e(\text{Sym}^d(B)) q^d = \frac{1}{(1-q)^{e(B)}}.$$

The lemma is essentially a consequence of the existence of a power structure on the Grothendieck group of varieties defined by symmetric products and the compatibility of the Euler characteristic homomorphism with that power structure. For convenience, we provide a direct proof here.

Proof. The d th symmetric product admits a stratification with strata labelled by partitions of d . Associated to any partition of d is a unique tuple (m_1, m_2, \dots) of non-negative integers with $\sum_{j=1}^{\infty} j m_j = d$. The stratum labelled by (m_1, m_2, \dots) parameterizes collections of points where there are m_j points of multiplicity j . The full stratification is given by

$$\text{Sym}^d(B) = \bigsqcup_{\substack{(m_1, m_2, \dots) \\ \sum_{j=1}^{\infty} j m_j = d}} \left\{ \left(\prod_{j=1}^{\infty} B^{m_j} \right) - \Delta \right\} / \prod_{j=1}^{\infty} \sigma_{m_j},$$

where by convention, B^0 is a point, Δ is the large diagonal, and σ_m is the m th symmetric group. Note that the function f_d is constant on each stratum and has value $\prod_{j=1}^{\infty} g(j)^{m_j}$. Note also that the action of $\prod_{j=1}^{\infty} \sigma_{m_j}$ on each stratum is free.

For schemes over \mathbb{C} , topological Euler characteristic is additive under stratification and multiplicative under maps which are (topological) fibrations. Thus

$$\int_{\text{Sym}^d(B)} G \, de = \sum_{\substack{(m_1, m_2, \dots) \\ \sum_{j=1}^{\infty} j m_j = d}} \left(\prod_{j=1}^{\infty} g(j)^{m_j} \right) \frac{e(B^{\sum_j m_j} - \Delta)}{m_1! m_2! m_3! \dots}.$$

For any natural number N , the projection $B^N - \Delta \rightarrow B^{N-1} - \Delta$ has fibers of the form $B - \{N - 1 \text{ points}\}$. The fibers have constant Euler characteristic given by $e(B) - (N - 1)$ and consequently, $e(B^N - \Delta) = (e(B) - (N - 1)) \cdot e(B^{N-1} - \Delta)$. Thus by induction, we find $e(B^N - \Delta) = e(B) \cdot (e(B) - 1) \cdots (e(B) - (N - 1))$ and so

$$\frac{e(B^{\sum_j m_j} - \Delta)}{m_1! m_2! m_3! \cdots} = \binom{e(B)}{m_1, m_2, m_3, \dots},$$

where the right hand side is the generalized multinomial coefficient.

Putting it together and applying the generalized multinomial theorem, we find

$$\begin{aligned} \sum_{d=0}^{\infty} q^d \int_{\text{Sym}^d(B)} G \, de &= \sum_{(m_1, m_2, \dots)} \prod_{j=1}^{\infty} (g(j)q^j)^{m_j} \binom{e(B)}{m_1, m_2, m_3, \dots} \\ &= \left(1 + \sum_{j=1}^{\infty} g(j)q^j \right)^{e(B)}, \end{aligned}$$

which proves the lemma. \square
